Programming Language—Common Lisp

22. Printer

22.1 The Lisp Printer

22.1.1 Overview of The Lisp Printer

Common Lisp provides a representation of most *objects* in the form of printed text called the printed representation. Functions such as **print** take an *object* and send the characters of its printed representation to a *stream*. The collection of routines that does this is known as the (Common Lisp) printer.

Reading a printed representation typically produces an object that is **equal** to the originally printed object.

22.1.1.1 Multiple Possible Textual Representations

Most *objects* have more than one possible textual representation. For example, the positive *integer* with a magnitude of twenty-seven can be textually expressed in any of these ways:

```
27 27. #o33 #x1B #b11011 #.(* 3 3 3) 81/3
```

A list containing the two symbols A and B can also be textually expressed in a variety of ways:

```
(AB) (ab) (ab) (\A|B|)
(|\A|
B
```

In general, from the point of view of the *Lisp reader*, wherever *whitespace* is permissible in a textual representation, any number of *spaces* and *newlines* can appear in *standard syntax*.

When a function such as **print** produces a printed representation, it must choose from among many possible textual representations. In most cases, it chooses a program readable representation, but in certain cases it might use a more compact notation that is not program-readable.

A number of option variables, called **printer control variables**, are provided to permit control of individual aspects of the printed representation of *objects*. Figure 22–1 shows the *standardized printer control variables*; there might also be *implementation-defined printer control variables*.

```
*print-array* *print-gensym* *print-pprint-dispatch*

*print-base* *print-length* *print-pretty*

*print-case* *print-level* *print-radix*

*print-circle* *print-lines* *print-readably*

*print-escape* *print-miser-width* *print-right-margin*
```

Figure 22-1. Standardized Printer Control Variables

In addition to the *printer control variables*, the following additional *defined names* relate to or affect the behavior of the *Lisp printer*:

package	*read-eval*	readtable-case	
read-default-float-format	*readtable $*$		

Figure 22-2. Additional Influences on the Lisp printer.

22.1.1.1.1 Printer Escaping

The variable *print-escape* controls whether the Lisp printer tries to produce notations such as escape characters and package prefixes.

The variable *print-readably* can be used to override many of the individual aspects controlled by the other printer control variables when program-readable output is especially important.

One of the many effects of making the *value* of *print-readably* be *true* is that the *Lisp printer* behaves as if *print-escape* were also *true*. For notational convenience, we say that if the value of either *print-readably* or *print-escape* is *true*, then *printer escaping* is "enabled"; and we say that if the values of both *print-readably* and *print-escape* are *false*, then *printer escaping* is "disabled".

22.1.2 Printer Dispatching

The Lisp printer makes its determination of how to print an object as follows:

If the value of *print-pretty* is true, printing is controlled by the current pprint dispatch table; see Section 22.2.1.4 (Pretty Print Dispatch Tables).

Otherwise (if the *value* of ***print-pretty*** is *false*), the object's **print-object** method is used; see Section 22.1.3 (Default Print-Object Methods).

22.1.3 Default Print-Object Methods

This section describes the default behavior of **print-object** methods for the *standardized types*.

22.1.3.1 Printing Numbers

22.1.3.1.1 Printing Integers

Integers are printed in the radix specified by the current output base in positional notation, most significant digit first. If appropriate, a radix specifier can be printed; see *print-radix*. If an integer is negative, a minus sign is printed and then the absolute value of the integer is printed. The integer zero is represented by the single digit 0 and never has a sign. A decimal point might be printed, depending on the value of *print-radix*.

For related information about the syntax of an *integer*, see Section 2.3.2.1.1 (Syntax of an Integer).

22.1.3.1.2 Printing Ratios

Ratios are printed as follows: the absolute value of the numerator is printed, as for an *integer*; then a /; then the denominator. The numerator and denominator are both printed in the radix specified by the *current output base*; they are obtained as if by **numerator** and **denominator**, and so *ratios* are printed in reduced form (lowest terms). If appropriate, a radix specifier can be printed; see *print-radix*. If the ratio is negative, a minus sign is printed before the numerator.

For related information about the syntax of a ratio, see Section 2.3.2.1.2 (Syntax of a Ratio).

22.1.3.1.3 Printing Floats

If the magnitude of the *float* is either zero or between 10^{-3} (inclusive) and 10^{7} (exclusive), it is printed as the integer part of the number, then a decimal point, followed by the fractional part of the number; there is always at least one digit on each side of the decimal point. If the sign of the number (as determined by **float-sign**) is negative, then a minus sign is printed before the number. If the format of the number does not match that specified by ***read-default-float-format***, then the *exponent marker* for that format and the digit 0 are also printed. For example, the base of the natural logarithms as a *short float* might be printed as 2.71828SO.

For non-zero magnitudes outside of the range 10^{-3} to 10^{7} , a *float* is printed in computerized scientific notation. The representation of the number is scaled to be between 1 (inclusive) and 10 (exclusive) and then printed, with one digit before the decimal point and at least one digit after the decimal point. Next the *exponent marker* for the format is printed, except that if the format of the number matches that specified by *read-default-float-format*, then the *exponent marker* E is used. Finally, the power of ten by which the fraction must be multiplied to equal the original number is printed as a decimal integer. For example, Avogadro's number as a *short float* is printed as 6.02523.

For related information about the syntax of a *float*, see Section 2.3.2.2 (Syntax of a Float).

22.1.3.1.4 Printing Complexes

A *complex* is printed as #C, an open parenthesis, the printed representation of its real part, a space, the printed representation of its imaginary part, and finally a close parenthesis.

For related information about the syntax of a *complex*, see Section 2.3.2.3 (Syntax of a Complex) and Section 2.4.8.11 (Sharpsign C).

22.1.3.1.5 Note about Printing Numbers

The printed representation of a number must not contain *escape characters*; see Section 2.3.1.1.1 (Escape Characters and Potential Numbers).

22.1.3.2 Printing Characters

When printer escaping is disabled, a character prints as itself; it is sent directly to the output stream. When printer escaping is enabled, then #\ syntax is used.

When the printer types out the name of a *character*, it uses the same table as the #\ reader macro would use; therefore any *character* name that is typed out is acceptable as input (in that *implementation*). If a non-graphic character has a standardized name₅, that name is preferred over non-standard names for printing in #\ notation. For the graphic standard characters, the character itself is always used for printing in #\ notation—even if the *character* also has a $name_5$.

For details about the #\ reader macro, see Section 2.4.8.1 (Sharpsign Backslash).

22.1.3.3 Printing Symbols

When *printer escaping* is disabled, only the characters of the *symbol*'s *name* are output (but the case in which to print characters in the *name* is controlled by *print-case*; see Section 22.1.3.3.2 (Effect of Readtable Case on the Lisp Printer)).

The remainder of this section applies only when *printer escaping* is enabled.

When printing a *symbol*, the printer inserts enough *single escape* and/or *multiple escape* characters (*backslashes* and/or *vertical-bars*) so that if **read** were called with the same ***readtable*** and with ***read-base*** bound to the *current output base*, it would return the same *symbol* (if it is not apparently uninterned) or an uninterned symbol with the same *print name* (otherwise).

For example, if the *value* of *print-base* were 16 when printing the symbol face, it would have to be printed as \FACE or \Face or |FACE|, because the token face would be read as a hexadecimal number (decimal value 64206) if the *value* of *read-base* were 16.

For additional restrictions concerning characters with nonstandard *syntax types* in the *current readtable*, see the *variable* *print-readably*

For information about how the $Lisp\ reader$ parses symbols, see Section 2.3.4 (Symbols as Tokens) and Section 2.4.8.5 (Sharpsign Colon).

nil might be printed as () when *print-pretty* is true and printer escaping is enabled.

22.1.3.3.1 Package Prefixes for Symbols

Package prefixes are printed if necessary. The rules for package prefixes are as follows. When the symbol is printed, if it is in the KEYWORD package, then it is printed with a preceding colon; otherwise, if it is accessible in the current package, it is printed without any package prefix; otherwise, it is printed with a package prefix.

A symbol that is apparently uninterned is printed preceded by "#:" if *print-gensym* is true and printer escaping is enabled; if *print-gensym* is false or printer escaping is disabled, then the symbol is printed without a prefix, as if it were in the current package.

Because the #: syntax does not intern the following symbol, it is necessary to use circular-list syntax if *print-circle* is true and the same uninterned symbol appears several times in an expression to be printed. For example, the result of

```
(let ((x (make-symbol "F00"))) (list x x))
```

would be printed as (#:foo #:foo) if *print-circle* were false, but as (#1=#:foo #1#) if *print-circle* were true.

A summary of the preceding package prefix rules follows:

foo:bar

foo:bar is printed when symbol bar is external in its home package foo and is not accessible in the current package.

foo::bar

foo::bar is printed when bar is internal in its home package foo and is not accessible in the current package.

:bar

:bar is printed when the home package of bar is the KEYWORD package.

#:bar

#:bar is printed when bar is apparently uninterned, even in the pathological case that bar has no home package but is nevertheless somehow accessible in the current package.

22.1.3.3.2 Effect of Readtable Case on the Lisp Printer

When printer escaping is disabled, or the characters under consideration are not already quoted specifically by single escape or multiple escape syntax, the readtable case of the current readtable affects the way the Lisp printer writes symbols in the following ways:

:upcase

When the *readtable case* is :upcase, *uppercase characters* are printed in the case specified by *print-case*, and *lowercase characters* are printed in their own case.

:downcase

When the readtable case is :downcase, uppercase characters are printed in their own case, and lowercase characters are printed in the case specified by *print-case*.

:preserve

When the readtable case is :preserve, all alphabetic characters are printed in their own case.

:invert

When the readtable case is :invert, the case of all alphabetic characters in single case symbol names is inverted. Mixed-case symbol names are printed as is.

The rules for escaping *alphabetic characters* in symbol names are affected by the **readtable-case** if *printer escaping* is enabled. *Alphabetic characters* are escaped as follows:

:upcase

When the readtable case is :upcase, all lowercase characters must be escaped.

:downcase

When the readtable case is :downcase, all uppercase characters must be escaped.

:preserve

When the readtable case is :preserve, no alphabetic characters need be escaped.

:invert

When the readtable case is :invert, no alphabetic characters need be escaped.

22.1.3.3.2.1 Examples of Effect of Readtable Case on the Lisp Printer

(string-upcase readtable-case)
(string-upcase print-case)
(symbol-name symbol)
(prin1-to-string symbol)))))))

The output from (test-readtable-case-printing) should be as follows:

READTABLE-CASE	*PRINT-CASE*	Symbol-name	Output
:UPCASE	:UPCASE	ZEBRA	ZEBRA
:UPCASE	:UPCASE	Zebra	Zebra
:UPCASE	:UPCASE	zebra	zebra
:UPCASE	:DOWNCASE	ZEBRA	zebra
:UPCASE	:DOWNCASE	Zebra	Zebra
:UPCASE	:DOWNCASE	zebra	zebra
:UPCASE	:CAPITALIZE	ZEBRA	Zebra
:UPCASE	:CAPITALIZE	Zebra	Zebra
:UPCASE	:CAPITALIZE	zebra	zebra
:DOWNCASE	:UPCASE	ZEBRA	ZEBRA
:DOWNCASE	:UPCASE	Zebra	Zebra
:DOWNCASE	:UPCASE	zebra	ZEBRA
:DOWNCASE	:DOWNCASE	ZEBRA	ZEBRA
:DOWNCASE	:DOWNCASE	Zebra	Zebra
:DOWNCASE	:DOWNCASE	zebra	zebra
:DOWNCASE	:CAPITALIZE	ZEBRA	ZEBRA
:DOWNCASE	:CAPITALIZE	Zebra	Zebra
:DOWNCASE	:CAPITALIZE	zebra	Zebra
:PRESERVE	:UPCASE	ZEBRA	ZEBRA
:PRESERVE	:UPCASE	Zebra	Zebra
:PRESERVE	:UPCASE	zebra	zebra
:PRESERVE	:DOWNCASE	ZEBRA	ZEBRA
:PRESERVE	:DOWNCASE	Zebra	Zebra
:PRESERVE	:DOWNCASE	zebra	zebra
:PRESERVE	:CAPITALIZE	ZEBRA	ZEBRA
:PRESERVE	:CAPITALIZE	Zebra	Zebra
:PRESERVE	:CAPITALIZE	zebra	zebra
:INVERT	:UPCASE	ZEBRA	zebra
:INVERT	:UPCASE	Zebra	Zebra
:INVERT	:UPCASE	zebra	ZEBRA
:INVERT	:DOWNCASE	ZEBRA	zebra
:INVERT	:DOWNCASE	Zebra	Zebra
:INVERT	:DOWNCASE	zebra	ZEBRA
:INVERT	:CAPITALIZE	ZEBRA	zebra
:INVERT	:CAPITALIZE	Zebra	Zebra
: INVERT	:CAPITALIZE	zebra	ZEBRA

22.1.3.4 Printing Strings

The characters of the *string* are output in order. If *printer escaping* is enabled, a *double-quote* is output before and after, and all *double-quotes* and *single escapes* are preceded by *backslash*. The printing of *strings* is not affected by *print-array*. Only the *active elements* of the *string* are printed.

For information on how the *Lisp reader* parses *strings*, see Section 2.4.5 (Double-Quote).

22.1.3.5 Printing Lists and Conses

Wherever possible, list notation is preferred over dot notation. Therefore the following algorithm is used to print a $cons \ x$:

- 1. A *left-parenthesis* is printed.
- 2. The car of x is printed.
- 3. If the cdr of x is itself a cons, it is made to be the current cons (i.e., x becomes that cons), a space is printed, and step 2 is re-entered.
- 4. If the cdr of x is not null, a space, a dot, a space, and the cdr of x are printed.
- 5. A right-parenthesis is printed.

Actually, the above algorithm is only used when *print-pretty* is false. When *print-pretty* is true (or when pprint is used), additional $whitespace_1$ may replace the use of a single space, and a more elaborate algorithm with similar goals but more presentational flexibility is used; see Section 22.1.2 (Printer Dispatching).

Although the two expressions below are equivalent, and the reader accepts either one and produces the same *cons*, the printer always prints such a *cons* in the second form.

```
(a . (b . ((c . (d . nil)) . (e . nil))))
(a b (c d) e)
```

The printing of *conses* is affected by *print-level*, *print-length*, and *print-circle*.

Following are examples of printed representations of *lists*:

```
(a . b) ;A dotted pair of a and b
(a.b) ;A list of one element, the symbol named a.b
(a . b) ;A list of two elements a. and b
(a . b) ;A list of two elements a and .b
```

```
(a b . c)
            ;A dotted list of a and b with c at the end; two conses
.iot
            ;The symbol whose name is .iot
(. b)
            ; Invalid - an error is signaled if an attempt is made to read
            ;this syntax.
(a .)
            ; Invalid - an error is signaled.
(a .. b)
            ;Invalid - an error is signaled.
(a . . b)
           ;Invalid - an error is signaled.
(a b c ...) ; Invalid - an error is signaled.
(a \. b)
            ;A list of three elements a, ., and b
(a | . | b)
          ;A list of three elements a, ., and b
(a \... b) ; A list of three elements a, ..., and b
(a \mid ... \mid b); A list of three elements a, ..., and b
```

For information on how the *Lisp reader* parses *lists* and *conses*, see Section 2.4.1 (Left-Parenthesis).

22.1.3.6 Printing Bit Vectors

A bit vector is printed as #* followed by the bits of the bit vector in order. If *print-array* is false, then the bit vector is printed in a format (using #<) that is concise but not readable. Only the active elements of the bit vector are printed.

For information on Lisp reader parsing of bit vectors, see Section 2.4.8.4 (Sharpsign Asterisk).

22.1.3.7 Printing Other Vectors

If *print-array* is true and *print-readably* is false, any vector other than a string or bit vector is printed using general-vector syntax; this means that information about specialized vector representations does not appear. The printed representation of a zero-length vector is #(). The printed representation of a non-zero-length vector begins with #(. Following that, the first element of the vector is printed. If there are any other elements, they are printed in turn, with each such additional element preceded by a space if *print-pretty* is false, or whitespace₁ if *print-pretty* is true. A right-parenthesis after the last element terminates the printed representation of the vector. The printing of vectors is affected by *print-level* and *print-length*. If the vector has a fill pointer, then only those elements below the fill pointer are printed.

If both *print-array* and *print-readably* are false, the vector is not printed as described above, but in a format (using #<) that is concise but not readable.

If *print-readably* is true, the vector prints in an implementation-defined manner; see the variable *print-readably*.

For information on how the *Lisp reader* parses these "other *vectors*," see Section 2.4.8.3 (Sharpsign Left-Parenthesis).

22.1.3.8 Printing Other Arrays

If *print-array* is true and *print-readably* is false, any array other than a vector is printed using #nA format. Let n be the rank of the array. Then # is printed, then n as a decimal integer, then A, then n open parentheses. Next the elements are scanned in row-major order, using write on each element, and separating elements from each other with whitespace₁. The array's dimensions are numbered 0 to n-1 from left to right, and are enumerated with the rightmost index changing fastest. Every time the index for dimension j is incremented, the following actions are taken:

- If j < n-1, then a close parenthesis is printed.
- If incrementing the index for dimension j caused it to equal dimension j, that index is reset to zero and the index for dimension j-1 is incremented (thereby performing these three steps recursively), unless j=0, in which case the entire algorithm is terminated. If incrementing the index for dimension j did not cause it to equal dimension j, then a space is printed.
- If j < n-1, then an open parenthesis is printed.

This causes the contents to be printed in a format suitable for :initial-contents to make-array. The lists effectively printed by this procedure are subject to truncation by *print-level* and *print-length*.

If the *array* is of a specialized *type*, containing bits or characters, then the innermost lists generated by the algorithm given above can instead be printed using bit-vector or string syntax, provided that these innermost lists would not be subject to truncation by *print-length*.

If both *print-array* and *print-readably* are false, then the array is printed in a format (using #<) that is concise but not readable.

If *print-readably* is true, the array prints in an implementation-defined manner; see the variable *print-readably*. In particular, this may be important for arrays having some dimension 0.

For information on how the *Lisp reader* parses these "other arrays," see Section 2.4.8.12 (Sharpsign A).

22.1.3.9 Examples of Printing Arrays

```
▷ ("<2,0>" "<2,1>" "<2,2>"))
▷ #("<0,0>" "<0,1>" "<0,2>" "<1,0>" "<1,1>" "<1,2>" "<2,0>" "<2,1>" "<2,2>")
→ #<ARRAY 9 indirect 36363476>
```

22.1.3.10 Printing Random States

A specific syntax for printing *objects* of *type* random-state is not specified. However, every *implementation* must arrange to print a *random state object* in such a way that, within the same implementation, read can construct from the printed representation a copy of the *random state* object as if the copy had been made by make-random-state.

If the type random state is effectively implemented by using the machinery for **defstruct**, the usual structure syntax can then be used for printing random state objects; one might look something like

```
#S(RANDOM-STATE :DATA #(14 49 98436589 786345 8734658324 ...))
```

where the components are *implementation-dependent*.

22.1.3.11 Printing Pathnames

When *printer escaping* is enabled, the syntax #P"..." is how a *pathname* is printed by **write** and the other functions herein described. The "..." is the namestring representation of the pathname.

When printer escaping is disabled, write writes a pathname P by writing (namestring P) instead.

For information on how the *Lisp reader* parses pathnames, see Section 2.4.8.14 (Sharpsign P).

22.1.3.12 Printing Structures

By default, a *structure* of type S is printed using #S syntax. This behavior can be customized by specifying a :print-function or :print-object option to the **defstruct** form that defines S, or by writing a **print-object** method that is specialized for objects of type S.

Different structures might print out in different ways; the default notation for structures is:

```
#S(structure-name {slot-key slot-value}*)
```

where #S indicates structure syntax, structure-name is a structure name, each slot-key is an initialization argument name for a slot in the structure, and each corresponding slot-value is a representation of the object in that slot.

For information on how the *Lisp reader* parses structures, see Section 2.4.8.13 (Sharpsign S).

22.1.3.13 Printing Other Objects

Other objects are printed in an *implementation-dependent* manner. It is not required that an *implementation* print those objects readably.

For example, hash tables, readtables, packages, streams, and functions might not print readably.

A common notation to use in this circumstance is #<...>. Since #< is not readable by the *Lisp* reader, the precise format of the text which follows is not important, but a common format to use is that provided by the **print-unreadable-object** macro.

For information on how the *Lisp reader* treats this notation, see Section 2.4.8.20 (Sharpsign Less-Than-Sign). For information on how to notate *objects* that cannot be printed *readably*, see Section 2.4.8.6 (Sharpsign Dot).

22.1.4 Examples of Printer Behavior

```
(let ((*print-escape* t)) (fresh-line) (write #\a))
> #\a
\rightarrow #\a
 (let ((*print-escape* nil) (*print-readably* nil))
   (fresh-line)
   (write #\a))
> a
\rightarrow #\a
 (progn (fresh-line) (prin1 #\a))
> #\a
\rightarrow #\a
 (progn (fresh-line) (print #\a))
> #\a
\rightarrow #\a
 (progn (fresh-line) (princ #\a))
⊳ a
\rightarrow #\a
 (dolist (val '(t nil))
   (let ((*print-escape* val) (*print-readably* val))
     (print '#\a)
     (prin1 #\a) (write-char #\Space)
     (princ #\a) (write-char #\Space)
     (write #\a)))
> #\a #\a a #\a
```

```
> #\a #\a a a
\rightarrow \, {\tt NIL}
 (progn (fresh-line) (write '(let ((a 1) (b 2)) (+ a b))))
▷ (LET ((A 1) (B 2)) (+ A B))
\rightarrow (LET ((A 1) (B 2)) (+ A B))
 (progn (fresh-line) (pprint '(let ((a 1) (b 2)) (+ a b))))
▷ (LET ((A 1)
        (B 2))
  (+ A B))

ightarrow (LET ((A 1) (B 2)) (+ A B))
 (progn (fresh-line)
        (write '(let ((a 1) (b 2)) (+ a b)) :pretty t))
(B 2))
▷ (+ A B))

ightarrow (LET ((A 1) (B 2)) (+ A B))
 (with-output-to-string (s)
    (write 'write :stream s)
    (prin1 'prin1 s))

ightarrow "WRITEPRIN1"
```

22.2 The Lisp Pretty Printer

22.2.1 Pretty Printer Concepts

The facilities provided by the **pretty printer** permit programs to redefine the way in which code is displayed, and allow the full power of pretty printing to be applied to complex combinations of data structures.

Whether any given style of output is in fact "pretty" is inherently a somewhat subjective issue. However, since the effect of the *pretty printer* can be customized by *conforming programs*, the necessary flexibility is provided for individual *programs* to achieve an arbitrary degree of aesthetic control.

By providing direct access to the mechanisms within the pretty printer that make dynamic decisions about layout, the macros and functions **pprint-logical-block**, **pprint-newline**, and **pprint-indent** make it possible to specify pretty printing layout rules as a part of any function that produces output. They also make it very easy for the detection of circularity and sharing, and abbreviation based on length and nesting depth to be supported by the function.

The pretty printer is driven entirely by dispatch based on the value of *print-print-dispatch*. The function set-print-dispatch makes it possible for conforming programs to associate new pretty printing functions with a type.

22.2.1.1 Dynamic Control of the Arrangement of Output

The actions of the *pretty printer* when a piece of output is too large to fit in the space available can be precisely controlled. Three concepts underlie the way these operations work—*logical blocks*, *conditional newlines*, and *sections*. Before proceeding further, it is important to define these terms.

The first line of Figure 22–3 shows a schematic piece of output. Each of the characters in the output is represented by "–". The positions of conditional newlines are indicated by digits. The beginnings and ends of logical blocks are indicated by "<" and ">" respectively.

The output as a whole is a logical block and the outermost section. This section is indicated by the 0's on the second line of Figure 1. Logical blocks nested within the output are specified by the macro **pprint-logical-block**. Conditional newline positions are specified by calls to **pprint-newline**. Each conditional newline defines two sections (one before it and one after it) and is associated with a third (the section immediately containing it).

The section after a conditional newline consists of: all the output up to, but not including, (a) the next conditional newline immediately contained in the same logical block; or if (a) is not applicable, (b) the next newline that is at a lesser level of nesting in logical blocks; or if (b) is not applicable, (c) the end of the output.

The section before a conditional newline consists of: all the output back to, but not including, (a) the previous conditional newline that is immediately contained in the same logical block; or if (a)

is not applicable, (b) the beginning of the immediately containing logical block. The last four lines in Figure 1 indicate the sections before and after the four conditional newlines.

The section immediately containing a conditional newline is the shortest section that contains the conditional newline in question. In Figure 22–3, the first conditional newline is immediately contained in the section marked with 0's, the second and third conditional newlines are immediately contained in the section before the fourth conditional newline, and the fourth conditional newline is immediately contained in the section after the first conditional newline.

Figure 22-3. Example of Logical Blocks, Conditional Newlines, and Sections

Whenever possible, the pretty printer displays the entire contents of a section on a single line. However, if the section is too long to fit in the space available, line breaks are inserted at conditional newline positions within the section.

22.2.1.2 Format Directive Interface

The primary interface to operations for dynamically determining the arrangement of output is provided through the functions and macros of the pretty printer. Figure 22–4 shows the defined names related to *pretty printing*.

print-lines	pprint-dispatch	pprint-pop
print-miser-width	pprint-exit-if-list-exhausted	pprint-tab
print-pprint-dispatch	pprint-fill	pprint-tabular
print-right-margin	pprint-indent	set-pprint-dispatch
copy-pprint-dispatch	pprint-linear	write
format	pprint-logical-block	
formatter	pprint-newline	

Figure 22-4. Defined names related to pretty printing.

Figure 22–5 identifies a set of *format directives* which serve as an alternate interface to the same pretty printing operations in a more textually compact form.

~I	~ W	~<~:>	
~:T	~//	~_	

Figure 22-5. Format directives related to Pretty Printing

22.2.1.3 Compiling Format Strings

A format string is essentially a program in a special-purpose language that performs printing, and that is interpreted by the function format. The formatter macro provides the efficiency of using a compiled function to do that same printing but without losing the textual compactness of format strings.

A **format control** is either a *format string* or a *function* that was returned by the the **formatter** macro.

22.2.1.4 Pretty Print Dispatch Tables

A **pprint dispatch table** is a mapping from keys to pairs of values. Each key is a *type specifier*. The values associated with a key are a "function" (specifically, a *function designator* or **nil**) and a "numerical priority" (specifically, a *real*). Basic insertion and retrieval is done based on the keys with the equality of keys being tested by **equal**.

When *print-pretty* is true, the current pprint dispatch table (in *print-pprint-dispatch*) controls how objects are printed. The information in this table takes precedence over all other mechanisms for specifying how to print objects. In particular, it has priority over user-defined print-object methods because the current pprint dispatch table is consulted first.

The function is chosen from the *current pprint dispatch table* by finding the highest priority function that is associated with a *type specifier* that matches the *object*; if there is more than one such function, it is *implementation-dependent* which is used.

However, if there is no information in the table about how to *pretty print* a particular kind of *object*, a *function* is invoked which uses **print-object** to print the *object*. The value of ***print-pretty*** is still *true* when this function is *called*, and individual methods for **print-object** might still elect to produce output in a special format conditional on the *value* of ***print-pretty***.

22.2.1.5 Pretty Printer Margins

A primary goal of pretty printing is to keep the output between a pair of margins. The column where the output begins is taken as the left margin. If the current column cannot be determined at the time output begins, the left margin is assumed to be zero. The right margin is controlled by *print-right-margin*.

22.2.2 Examples of using the Pretty Printer

As an example of the interaction of logical blocks, conditional newlines, and indentation, consider the function simple-pprint-defun below. This function prints out lists whose *cars* are defun in the standard way assuming that the list has exactly length 4.

```
(defun simple-pprint-defun (*standard-output* list)
  (pprint-logical-block (*standard-output* list :prefix "(" :suffix ")")
      (write (first list))
```

```
(write-char #\Space)
(pprint-newline :miser)
(pprint-indent :current 0)
(write (second list))
(write-char #\Space)
(pprint-newline :fill)
(write (third list))
(pprint-indent :block 1)
(write-char #\Space)
(pprint-newline :linear)
(write (fourth list))))
```

Suppose that one evaluates the following:

```
(simple-pprint-defun *standard-output* '(defun prod (x y) (* x y)))
```

If the line width available is greater than or equal to 26, then all of the output appears on one line. If the line width available is reduced to 25, a line break is inserted at the linear-style conditional newline before the *expression* (* x y), producing the output shown. The (pprint-indent:block 1) causes (* x y) to be printed at a relative indentation of 1 in the logical block.

```
(DEFUN PROD (X Y)
(* X Y))
```

If the line width available is 15, a line break is also inserted at the fill style conditional newline before the argument list. The call on (pprint-indent :current 0) causes the argument list to line up under the function name.

```
(DEFUN PROD
(X Y)
(* X Y))
```

If *print-miser-width* were greater than or equal to 14, the example output above would have been as follows, because all indentation changes are ignored in miser mode and line breaks are inserted at miser-style conditional newlines.

```
(DEFUN
PROD
(X Y)
(* X Y))
```

As an example of a per-line prefix, consider that evaluating the following produces the output shown with a line width of 20 and *print-miser-width* of nil.

```
(pprint-logical-block (*standard-output* nil :per-line-prefix ";;; ")
  (simple-pprint-defun *standard-output* '(defun prod (x y) (* x y))))
;;; (DEFUN PROD
```

```
;;; (X Y);;; (* X Y))
```

As a more complex (and realistic) example, consider the function pprint-let below. This specifies how to print a let form in the traditional style. It is more complex than the example above, because it has to deal with nested structure. Also, unlike the example above it contains complete code to readably print any possible list that begins with the symbol let. The outermost pprint-logical-block form handles the printing of the input list as a whole and specifies that parentheses should be printed in the output. The second pprint-logical-block form handles the list of binding pairs. Each pair in the list is itself printed by the innermost pprint-logical-block. (A loop form is used instead of merely decomposing the pair into two objects so that readable output will be produced no matter whether the list corresponding to the pair has one element, two elements, or (being malformed) has more than two elements.) A space and a fill-style conditional newline are placed after each pair except the last. The loop at the end of the topmost pprint-logical-block form prints out the forms in the body of the let form separated by spaces and linear-style conditional newlines.

```
(defun pprint-let (*standard-output* list)
  (pprint-logical-block (nil list :prefix "(" :suffix ")")
    (write (pprint-pop))
    (pprint-exit-if-list-exhausted)
    (write-char #\Space)
    (pprint-logical-block (nil (pprint-pop) :prefix "(" :suffix ")")
      (pprint-exit-if-list-exhausted)
      (loop (pprint-logical-block (nil (pprint-pop) :prefix "(" :suffix ")")
              (pprint-exit-if-list-exhausted)
              (loop (write (pprint-pop))
                    (pprint-exit-if-list-exhausted)
                    (write-char #\Space)
                    (pprint-newline :linear)))
            (pprint-exit-if-list-exhausted)
            (write-char #\Space)
            (pprint-newline :fill)))
    (pprint-indent :block 1)
    (loop (pprint-exit-if-list-exhausted)
          (write-char #\Space)
          (pprint-newline :linear)
          (write (pprint-pop)))))
```

Suppose that one evaluates the following with *print-level* being 4, and *print-circle* being true.

If the line length is greater than or equal to 77, the output produced appears on one line. However,

(LET (X

if the line length is 76, line breaks are inserted at the linear-style conditional newlines separating the forms in the body and the output below is produced. Note that, the degenerate binding pair x is printed readably even though it fails to be a list; a depth abbreviation marker is printed in place of $(g\ 3)$; the binding pair $(z\ .\ 2)$ is printed readably even though it is not a proper list; and appropriate circularity markers are printed.

If the line length is reduced to 35, a line break is inserted at one of the fill-style conditional newlines separating the binding pairs.

Suppose that the line length is further reduced to 22 and *print-length* is set to 3. In this situation, line breaks are inserted after both the first and second binding pairs. In addition, the second binding pair is itself broken across two lines. Clause (b) of the description of fill-style conditional newlines (see the *function* pprint-newline) prevents the binding pair (z . 2) from being printed at the end of the third line. Note that the length abbreviation hides the circularity from view and therefore the printing of circularity markers disappears.

Evaluating the following with a line length of 15 produces the output shown.

```
(pprint-vector *standard-output* '#(12 34 567 8 9012 34 567 89 0 1 23))
```

```
#(12 34 567 8 9012 34 567 89 0 1 23)
```

As examples of the convenience of specifying pretty printing with *format strings*, consider that the functions simple-pprint-defun and pprint-let used as examples above can be compactly defined as follows. (The function pprint-vector cannot be defined using **format** because the data structure it traverses is not a list.)

```
(defun simple-pprint-defun (*standard-output* list)
  (format T "~:<~W ~@_~:I~W ~:_~W~1I ~_~W~:>" list))
(defun pprint-let (*standard-output* list)
  (format T "~:<~W~^~:<~@{~:<~@{~:V~^~:_~}~:>~1I~@{~^~_~W~}~:>" list))
```

In the following example, the first form restores *print-pprint-dispatch* to the equivalent of its initial value. The next two forms then set up a special way to pretty print ratios. Note that the more specific type specifier has to be associated with a higher priority.

The following two forms illustrate the definition of pretty printing functions for types of code. The first form illustrates how to specify the traditional method for printing quoted objects using single-quote. Note the care taken to ensure that data lists that happen to begin with quote will be printed readably. The second form specifies that lists beginning with the symbol my-let should print the same way that lists beginning with let print when the initial pprint dispatch table is in effect.

```
(set-pprint-dispatch '(cons (member quote)) ()
  #'(lambda (s list)
      (if (and (consp (cdr list)) (null (cddr list)))
            (funcall (formatter "'~W") s (cadr list))
            (pprint-fill s list))))
```

The next example specifies a default method for printing lists that do not correspond to function calls. Note that the functions **pprint-linear**, **pprint-fill**, and **pprint-tabular** are all defined with optional *colon-p* and *at-sign-p* arguments so that they can be used as **pprint dispatch functions** as well as \sim/\ldots functions.

This final example shows how to define a pretty printing function for a user defined data structure.

The pretty printing function for the structure family specifies how to adjust the layout of the output so that it can fit aesthetically into a variety of line widths. In addition, it obeys the printer control variables *print-level*, *print-length*, *print-lines*, *print-circle* and *print-escape*, and can tolerate several different kinds of malformity in the data structure. The output below shows what is printed out with a right margin of 25, *print-pretty* being true, *print-escape* being false, and a malformed kids list.

Note that a pretty printing function for a structure is different from the structure's **print-object** method. While **print-object** methods are permanently associated with a structure, pretty printing functions are stored in pprint dispatch tables and can be rapidly changed to reflect different printing needs. If there is no pretty printing function for a structure in the current pprint dispatch table, its **print-object** method is used instead.

22.2.3 Notes about the Pretty Printer's Background

For a background reference to the abstract concepts detailed in this section, see XP: A Common Lisp Pretty Printing System. The details of that paper are not binding on this document, but may be helpful in establishing a conceptual basis for understanding this material.

22.3 Formatted Output

format is useful for producing nicely formatted text, producing good-looking messages, and so on. format can generate and return a *string* or output to *destination*.

The *control-string* argument to **format** is actually a *format control*. That is, it can be either a *format string* or a *function*, for example a *function* returned by the **formatter** *macro*.

If it is a function, the function is called with the appropriate output stream as its first argument and the data arguments to **format** as its remaining arguments. The function should perform whatever output is necessary and return the unused tail of the arguments (if any).

The compilation process performed by **formatter** produces a *function* that would do with its *arguments* as the **format** interpreter would do with those *arguments*.

The remainder of this section describes what happens if the *control-string* is a *format string*.

Control-string is composed of simple text (characters) and embedded directives.

format writes the simple text as is; each embedded directive specifies further text output that is to appear at the corresponding point within the simple text. Most directives use one or more elements of *args* to create their output.

A directive consists of a *tilde*, optional prefix parameters separated by commas, optional *colon* and *at-sign* modifiers, and a single character indicating what kind of directive this is. There is no required ordering between the *at-sign* and *colon* modifier. The *case* of the directive character is ignored. Prefix parameters are notated as signed (sign is optional) decimal numbers, or as a *single-quote* followed by a character. For example, ~5,'od can be used to print an *integer* in decimal radix in five columns with leading zeros, or ~5,'*d to get leading asterisks.

In place of a prefix parameter to a directive, V (or v) can be used. In this case, format takes an argument from args as a parameter to the directive. The argument should be an integer or character. If the arg used by a V parameter is nil, the effect is as if the parameter had been omitted. # can be used in place of a prefix parameter; it represents the number of args remaining to be processed. When used within a recursive format, in the context of ~? or ~{, the # prefix parameter represents the number of format arguments remaining within the recursive call.

Examples of format strings:

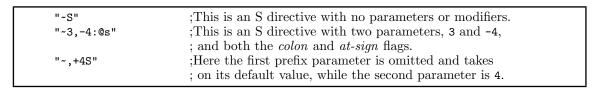

Figure 22-6. Examples of format control strings

format sends the output to destination. If destination is nil, format creates and returns a string

containing the output from *control-string*. If *destination* is *non-nil*, it must be a *string* with a *fill* pointer, a *stream*, or the symbol t. If *destination* is a *string* with a *fill* pointer, the output is added to the end of the *string*. If *destination* is a *stream*, the output is sent to that *stream*. If *destination* is t, the output is sent to *standard* output.

In the description of the directives that follows, the term *arg* in general refers to the next item of the set of *args* to be processed. The word or phrase at the beginning of each description is a mnemonic for the directive. **format** directives do not bind any of the printer control variables (*print-...*) except as specified in the following descriptions. Implementations may specify the binding of new, implementation-specific printer control variables for each **format** directive, but they may neither bind any standard printer control variables not specified in description of a **format** directive nor fail to bind any standard printer control variables as specified in the description.

22.3.1 FORMAT Basic Output

22.3.1.1 Tilde C: Character

The next arg should be a character; it is printed according to the modifier flags.

-C prints the *character* as if by using **write-char** if it is a *simple character*. Characters that are not *simple* are not necessarily printed as if by **write-char**, but are displayed in an *implementation-defined*, abbreviated format. For example,

```
(format nil "~C" #\A) \to "A" (format nil "~C" #\Space) \to " "
```

~:C is the same as ~C for *printing characters*, but other *characters* are "spelled out." The intent is that this is a "pretty" format for printing characters. For *simple characters* that are not *printing*, what is spelled out is the *name* of the *character* (see **char-name**). For *characters* that are not *simple* and not *printing*, what is spelled out is *implementation-defined*. For example,

```
(format nil "~:C" #\A) \rightarrow "A" (format nil "~:C" #\Space) \rightarrow "Space" ;; This next example assumes an implementation-defined "Control" attribute. (format nil "~:C" #\Control-Space) \rightarrow "Control-Space" \stackrel{or}{\rightarrow} "c-Space"
```

~:@C prints what ~: C would, and then if the *character* requires unusual shift keys on the keyboard to type it, this fact is mentioned. For example,

```
(format nil "~:@C" #\Control-Partial) 
ightarrow "Control-\partial (Top-F)"
```

This is the format used for telling the user about a key he is expected to type, in prompts, for instance. The precise output may depend not only on the implementation, but on the particular I/O devices in use.

~@C prints the *character* in a way that the *Lisp reader* can understand, using #\ syntax.

~@C binds *print-escape* to t.

22.3.1.2 Tilde Percent: Newline

This outputs a #\Newline character, thereby terminating the current output line and beginning a new one. $\sim n\%$ outputs n newlines. No arg is used.

22.3.1.3 Tilde Ampersand: Fresh-Line

Unless it can be determined that the output stream is already at the beginning of a line, this outputs a newline. -n& calls **fresh-line** and then outputs n-1 newlines. -0& does nothing.

22.3.1.4 Tilde Vertical-Bar: Page

This outputs a page separator character, if possible. $\neg n \mid$ does this n times.

22.3.1.5 Tilde Tilde: Tilde

This outputs a *tilde*. $\neg n \neg$ outputs n tildes.

22.3.2 FORMAT Radix Control

22.3.2.1 Tilde R: Radix

~nR prints arg in radix n. The modifier flags and any remaining parameters are used as for the ~D directive. ~D is the same as ~10R. The full form is ~radix, mincol, padchar, commachar, comma-intervalR.

If no prefix parameters are given to ~R, then a different interpretation is given. The argument should be an *integer*. For example, if *arg* is 4:

- ~R prints arg as a cardinal English number: four.
- ~: R prints arg as an ordinal English number: fourth.
- ~@R prints arg as a Roman numeral: IV.

• ~: CR prints arg as an old Roman numeral: IIII.

For example:

```
(format nil "~,",4:B" 13) \rightarrow "1101" (format nil "~,",4:B" 17) \rightarrow "1 0001" (format nil "~19,0,",4:B" 3333) \rightarrow "0000 1101 0000 0101" (format nil "~3,,",2:R" 17) \rightarrow "1 22" (format nil "~,",2:D" #xFFFF) \rightarrow "6|55|35"
```

If and only if the first parameter, n, is supplied, $\neg R$ binds *print-escape* to false, *print-radix* to false, *print-base* to n, and *print-readably* to false.

If and only if no parameters are supplied, ~R binds *print-base* to 10.

22.3.2.2 Tilde D: Decimal

An arg, which should be an integer, is printed in decimal radix. ~D will never put a decimal point after the number.

~mincolD uses a column width of mincol; spaces are inserted on the left if the number requires fewer than mincol columns for its digits and sign. If the number doesn't fit in mincol columns, additional columns are used as needed.

~mincol, padcharD uses padchar as the pad character instead of space.

If arg is not an integer, it is printed in ~A format and decimal base.

The @ modifier causes the number's sign to be printed always; the default is to print it only if the number is negative. The : modifier causes commas to be printed between groups of digits; commachar may be used to change the character used as the comma. comma-interval must be an integer and defaults to 3. When the : modifier is given to any of these directives, the commachar is printed between groups of comma-interval digits.

Thus the most general form of ~D is ~mincol, padchar, commachar, comma-intervalD.

~D binds *print-escape* to false, *print-radix* to false, *print-base* to 10, and *print-readably* to false.

22.3.2.3 Tilde B: Binary

This is just like $\sim D$ but prints in binary radix (radix 2) instead of decimal. The full form is therefore $\sim mincol$, padchar, commachar, comma-intervalB.

~B binds *print-escape* to false, *print-radix* to false, *print-base* to 2, and *print-readably* to false.

22.3.2.4 Tilde O: Octal

This is just like ~D but prints in octal radix (radix 8) instead of decimal. The full form is therefore ~mincol, padchar, commachar, comma-intervalO.

~0 binds *print-escape* to false, *print-radix* to false, *print-base* to 8, and *print-readably* to false.

22.3.2.5 Tilde X: Hexadecimal

This is just like ~D but prints in hexadecimal radix (radix 16) instead of decimal. The full form is therefore ~mincol, padchar, commachar, comma-intervalx.

~X binds *print-escape* to false, *print-radix* to false, *print-base* to 16, and *print-readably* to false.

22.3.3 FORMAT Floating-Point Printers

22.3.3.1 Tilde F: Fixed-Format Floating-Point

The next arg is printed as a float.

The full form is $\neg w$, d, k, overflowchar, padchar. The parameter w is the width of the field to be printed; d is the number of digits to print after the decimal point; k is a scale factor that defaults to zero.

Exactly w characters will be output. First, leading copies of the character padchar (which defaults to a space) are printed, if necessary, to pad the field on the left. If the arg is negative, then a minus sign is printed; if the arg is not negative, then a plus sign is printed if and only if the $\mathfrak E$ modifier was supplied. Then a sequence of digits, containing a single embedded decimal point, is printed; this represents the magnitude of the value of arg times 10^k , rounded to d fractional digits. When rounding up and rounding down would produce printed values equidistant from the scaled value of arg, then the implementation is free to use either one. For example, printing the argument 6.375 using the format ~4,2F may correctly produce either 6.37 or 6.38. Leading zeros are not permitted, except that a single zero digit is output before the decimal point if the printed value is less than one, and this single zero digit is not output at all if w=d+1.

If it is impossible to print the value in the required format in a field of width w, then one of two actions is taken. If the parameter overflowchar is supplied, then w copies of that parameter are printed instead of the scaled value of arg. If the overflowchar parameter is omitted, then the scaled value is printed using more than w characters, as many more as may be needed.

If the w parameter is omitted, then the field is of variable width. In effect, a value is chosen for w in such a way that no leading pad characters need to be printed and exactly d characters will follow the decimal point. For example, the directive \sim , 2F will print exactly two digits after the decimal point and as many as necessary before the decimal point.

If the parameter d is omitted, then there is no constraint on the number of digits to appear after the decimal point. A value is chosen for d in such a way that as many digits as possible may be printed subject to the width constraint imposed by the parameter w and the constraint that no trailing zero digits may appear in the fraction, except that if the fraction to be printed is zero, then a single zero digit should appear after the decimal point if permitted by the width constraint.

If both w and d are omitted, then the effect is to print the value using ordinary free-format output; **prin1** uses this format for any number whose magnitude is either zero or between 10^{-3} (inclusive) and 10^{7} (exclusive).

If w is omitted, then if the magnitude of arg is so large (or, if d is also omitted, so small) that more than 100 digits would have to be printed, then an implementation is free, at its discretion, to print the number using exponential notation instead, as if by the directive \sim E (with all parameters to \sim E defaulted, not taking their values from the \sim F directive).

If arg is a rational number, then it is coerced to be a single float and then printed. Alternatively, an implementation is permitted to process a rational number by any other method that has essentially the same behavior but avoids loss of precision or overflow because of the coercion. If w and d are not supplied and the number has no exact decimal representation, for example 1/3, some precision cutoff must be chosen by the implementation since only a finite number of digits may be printed.

If arg is a complex number or some non-numeric object, then it is printed using the format directive $\sim wD$, thereby printing it in decimal radix and a minimum field width of w.

~F binds *print-escape* to false and *print-readably* to false.

22.3.3.2 Tilde E: Exponential Floating-Point

The next arg is printed as a float in exponential notation.

The full form is $\sim w$, d, e, k, overflowchar, padchar, exponentchar. The parameter w is the width of the field to be printed; d is the number of digits to print after the decimal point; e is the number of digits to use when printing the exponent; k is a scale factor that defaults to one (not zero).

Exactly w characters will be output. First, leading copies of the character padchar (which defaults to a space) are printed, if necessary, to pad the field on the left. If the arg is negative, then a minus sign is printed; if the arg is not negative, then a plus sign is printed if and only if the @ modifier was supplied. Then a sequence of digits containing a single embedded decimal point is printed. The form of this sequence of digits depends on the scale factor k. If k is zero, then d digits are printed after the decimal point, and a single zero digit appears before the decimal point if the total field width will permit it. If k is positive, then it must be strictly less than d+2; k significant digits are printed before the decimal point, and d-k+1 digits are printed after the decimal point. If k is negative, then it must be strictly greater than -d; a single zero digit appears before the decimal point if the total field width will permit it, and after the decimal point are printed first -k zeros and then d+k significant digits. The printed fraction must be properly rounded. When rounding up and rounding down would produce printed values equidistant from the scaled value of arg, then the implementation is free to use either one. For example, printing the argument 637.5 using the format ~8,2E may correctly produce either 6.37E+2 or 6.38E+2.

Following the digit sequence, the exponent is printed. First the character parameter exponentchar is printed; if this parameter is omitted, then the exponent marker that **prin1** would use is printed, as determined from the type of the float and the current value of *read-default-float-format*. Next, either a plus sign or a minus sign is printed, followed by e digits representing the power of ten by which the printed fraction must be multiplied to properly represent the rounded value of ara.

If it is impossible to print the value in the required format in a field of width w, possibly because k is too large or too small or because the exponent cannot be printed in e character positions, then one of two actions is taken. If the parameter overflowchar is supplied, then w copies of that parameter are printed instead of the scaled value of arg. If the overflowchar parameter is omitted, then the scaled value is printed using more than w characters, as many more as may be needed; if the problem is that d is too small for the supplied k or that e is too small, then a larger value is used for d or e as may be needed.

If the w parameter is omitted, then the field is of variable width. In effect a value is chosen for w in such a way that no leading pad characters need to be printed.

If the parameter d is omitted, then there is no constraint on the number of digits to appear. A value is chosen for d in such a way that as many digits as possible may be printed subject to the width constraint imposed by the parameter w, the constraint of the scale factor k, and the constraint that no trailing zero digits may appear in the fraction, except that if the fraction to be printed is zero then a single zero digit should appear after the decimal point.

If the parameter e is omitted, then the exponent is printed using the smallest number of digits necessary to represent its value.

If all of w, d, and e are omitted, then the effect is to print the value using ordinary free-format exponential-notation output; **prin1** uses a similar format for any non-zero number whose magnitude is less than 10^{-3} or greater than or equal to 10^{7} . The only difference is that the ~E directive always prints a plus or minus sign in front of the exponent, while **prin1** omits the plus sign if the exponent is non-negative.

If arg is a rational number, then it is coerced to be a single float and then printed. Alternatively, an implementation is permitted to process a rational number by any other method that has essentially the same behavior but avoids loss of precision or overflow because of the coercion. If w and d are unsupplied and the number has no exact decimal representation, for example 1/3, some precision cutoff must be chosen by the implementation since only a finite number of digits may be printed.

If arg is a complex number or some non-numeric object, then it is printed using the format directive $\sim wD$, thereby printing it in decimal radix and a minimum field width of w.

~E binds *print-escape* to false and *print-readably* to false.

22.3.3.3 Tilde G: General Floating-Point

The next arg is printed as a float in either fixed-format or exponential notation as appropriate.

The full form is $\sim w$, d, e, k, overflowchar, padchar, exponentcharG. The format in which to print arg depends on the magnitude (absolute value) of the arg. Let n be an integer such that $10^{n-1} \le |arg| < 10^n$. Let ee equal e+2, or 4 if e is omitted. Let ww equal w-ee, or nil if w is omitted. If d is omitted, first let q be the number of digits needed to print arg with no loss of information and without leading or trailing zeros; then let d equal (max q (min n 7)). Let dd equal d-n.

If $0 \le dd \le d$, then arg is printed as if by the format directives

~ww,dd,overflowchar,padcharF~ee@T

Note that the scale factor k is not passed to the ~F directive. For all other values of dd, arg is printed as if by the format directive

 $\sim w$, d, e, k, overflowchar, padchar, exponentcharE

In either case, an @ modifier is supplied to the $\sim F$ or $\sim E$ directive if and only if one was supplied to the $\sim G$ directive.

~G binds *print-escape* to false and *print-readably* to false.

22.3.3.4 Tilde Dollarsign: Monetary Floating-Point

The next arg is printed as a float in fixed-format notation.

The full form is $\neg d$, n, w, padchar\$. The parameter d is the number of digits to print after the decimal point (default value 2); n is the minimum number of digits to print before the decimal point (default value 1); w is the minimum total width of the field to be printed (default value 0).

First padding and the sign are output. If the arg is negative, then a minus sign is printed; if the arg is not negative, then a plus sign is printed if and only if the $\mathfrak o$ modifier was supplied. If the : modifier is used, the sign appears before any padding, and otherwise after the padding. If w is supplied and the number of other characters to be output is less than w, then copies of padchar (which defaults to a space) are output to make the total field width equal w. Then n digits are printed for the integer part of arg, with leading zeros if necessary; then a decimal point; then d digits of fraction, properly rounded.

If the magnitude of arg is so large that more than m digits would have to be printed, where m is the larger of w and 100, then an implementation is free, at its discretion, to print the number using exponential notation instead, as if by the directive $\neg w$, $q_{""}padchar$ E, where w and padchar are present or omitted according to whether they were present or omitted in the \neg \$ directive, and where q=d+n-1, where d and n are the (possibly default) values given to the \neg \$ directive.

If arg is a rational number, then it is coerced to be a single float and then printed. Alternatively, an implementation is permitted to process a rational number by any other method that has essentially the same behavior but avoids loss of precision or overflow because of the coercion.

If arg is a complex number or some non-numeric object, then it is printed using the format directive $\sim wD$, thereby printing it in decimal radix and a minimum field width of w.

~\$ binds *print-escape* to false and *print-readably* to false.

22.3.4 FORMAT Printer Operations

22.3.4.1 Tilde A: Aesthetic

An arg, any object, is printed without escape characters (as by **princ**). If arg is a string, its characters will be output verbatim. If arg is **nil** it will be printed as **nil**; the colon modifier (~:A) will cause an arg of **nil** to be printed as (), but if arg is a composite structure, such as a list or vector, any contained occurrences of **nil** will still be printed as **nil**.

 \sim mincol Δ inserts spaces on the right, if necessary, to make the width at least mincol columns. The Δ modifier causes the spaces to be inserted on the left rather than the right.

~mincol, colinc, minpad, padcharA is the full form of ~A, which allows control of the padding. The string is padded on the right (or on the left if the @ modifier is used) with at least minpad copies of padchar; padding characters are then inserted colinc characters at a time until the total width is at least mincol. The defaults are 0 for mincol and minpad, 1 for colinc, and the space character for padchar.

~A binds *print-escape* to false, and *print-readably* to false.

22.3.4.2 Tilde S: Standard

This is just like ~A, but *arg* is printed with escape characters (as by **prin1** rather than **princ**). The output is therefore suitable for input to **read**. ~S accepts all the arguments and modifiers that ~A does.

~S binds *print-escape* to t.

22.3.4.3 Tilde W: Write

An argument, any *object*, is printed obeying every printer control variable (as by **write**). In addition, ~W interacts correctly with depth abbreviation, by not resetting the depth counter to zero. ~W does not accept parameters. If given the *colon* modifier, ~W binds *print-pretty* to *true*. If given the *at-sign* modifier, ~W binds *print-level* and *print-length* to nil.

~W provides automatic support for the detection of circularity and sharing. If the *value* of *print-circle* is not nil and ~W is applied to an argument that is a circular (or shared) reference, an appropriate #n# marker is inserted in the output instead of printing the argument.

22.3.5 FORMAT Pretty Printer Operations

The following constructs provide access to the *pretty printer*:

22.3.5.1 Tilde Underscore: Conditional Newline

Without any modifiers, ~_ is the same as (pprint-newline :linear). ~@_ is the same as (pprint-newline :miser). ~:_ is the same as (pprint-newline :fill). ~:@_ is the same as (pprint-newline :mandatory).

22.3.5.2 Tilde Less-Than-Sign: Logical Block

~<...~:>

If ~:> is used to terminate a ~<...~>, the directive is equivalent to a call to **pprint-logical-block**. The argument corresponding to the ~<...~:> directive is treated in the same way as the *list* argument to **pprint-logical-block**, thereby providing automatic support for non-*list* arguments and the detection of circularity, sharing, and depth abbreviation. The portion of the *control-string* nested within the ~<...~:> specifies the :prefix (or :per-line-prefix), :suffix, and body of the **pprint-logical-block**.

The *control-string* portion enclosed by ~<...~:> can be divided into segments ~<*prefix*~; *body*~; *suffix*~:> by ~; directives. If the first section is terminated by ~@;, it specifies a per-line prefix rather than a simple prefix. The *prefix* and *suffix* cannot contain format directives. An error is signaled if either the prefix or suffix fails to be a constant string or if the enclosed portion is divided into more than three segments.

If the enclosed portion is divided into only two segments, the *suffix* defaults to the null string. If the enclosed portion consists of only a single segment, both the *prefix* and the *suffix* default to the null string. If the *colon* modifier is used (*i.e.*, ~:<...~:>), the *prefix* and *suffix* default to "(" and ")" (respectively) instead of the null string.

The body segment can be any arbitrary *format string*. This *format string* is applied to the elements of the list corresponding to the ~<...~:> directive as a whole. Elements are extracted from this list using **pprint-pop**, thereby providing automatic support for malformed lists, and the detection of circularity, sharing, and length abbreviation. Within the body segment, ~^ acts like **pprint-exit-if-list-exhausted**.

~<...~:> supports a feature not supported by **pprint-logical-block**. If $\sim: @>$ is used to terminate the directive (*i.e.*, ~<...~:@>), then a fill-style conditional newline is automatically inserted after each group of blanks immediately contained in the body (except for blanks after a $\langle Newline \rangle$ directive). This makes it easy to achieve the equivalent of paragraph filling.

If the at-sign modifier is used with ~<...~:>, the entire remaining argument list is passed to the directive as its argument. All of the remaining arguments are always consumed by ~@<...~:>, even if they are not all used by the format string nested in the directive. Other than the difference in its argument, ~@<...~:> is exactly the same as ~<...~:> except that circularity detection is not applied if ~@<...~:> is encountered at top level in a format string. This ensures that circularity detection is applied only to data lists, not to format argument lists.

". #n#" is printed if circularity or sharing has to be indicated for its argument as a whole.

To a considerable extent, the basic form of the directive ~<...~> is incompatible with the dynamic control of the arrangement of output by ~W, ~_, ~<...~:>, ~I, and ~:T. As a result, an error is signaled if any of these directives is nested within ~<...~>. Beyond this, an error is also signaled if the ~<...~> form of ~<...~> is used in the same format string with ~W, ~_, ~<...~:>, ~I, or ~:T.

See also Section 22.3.6.2 (Tilde Less-Than-Sign: Justification).

22.3.5.3 Tilde I: Indent

~nI is the same as (pprint-indent :block n).

 $\sim n$: I is the same as (pprint-indent :current n). In both cases, n defaults to zero, if it is omitted.

22.3.5.4 Tilde Slash: Call Function

~/name/

User defined functions can be called from within a format string by using the directive ~/name/. The colon modifier, the at-sign modifier, and arbitrarily many parameters can be specified with the ~/name/ directive. name can be any arbitrary string that does not contain a "/". All of the characters in name are treated as if they were upper case. If name contains a single colon (:) or double colon (::), then everything up to but not including the first ":" or "::" is taken to be a string that names a package. Everything after the first ":" or "::" (if any) is taken to be a string that names a symbol. The function corresponding to a ~/name/ directive is obtained by looking up the symbol that has the indicated name in the indicated package. If name does not contain a ":" or "::", then the whole name string is looked up in the COMMON-LISP-USER package.

When a ~/name/ directive is encountered, the indicated function is called with four or more arguments. The first four arguments are: the output stream, the format argument corresponding to the directive, a generalized boolean that is true if the colon modifier was used, and a generalized boolean that is true if the at-sign modifier was used. The remaining arguments consist of any parameters specified with the directive. The function should print the argument appropriately. Any values returned by the function are ignored.

The three functions pprint-linear, pprint-fill, and pprint-tabular are specifically designed so that they can be called by ~/.../ (i.e., ~/pprint-linear/, ~/pprint-fill/, and ~/pprint-tabular/). In particular they take colon and at-sign arguments.

22.3.6 FORMAT Layout Control

22.3.6.1 Tilde T: Tabulate

This spaces over to a given column. $\sim colnum$, colincT will output sufficient spaces to move the cursor to column colnum. If the cursor is already at or beyond column colnum, it will output spaces to move it to column colnum+k*colinc for the smallest positive integer k possible, unless colinc is zero, in which case no spaces are output if the cursor is already at or beyond column colnum, colnum and colinc default to 1.

If for some reason the current absolute column position cannot be determined by direct inquiry, format may be able to deduce the current column position by noting that certain directives (such as ~%, or ~& with the argument being a string containing a newline) cause the column position to be reset to zero, and counting the number of characters emitted since that point. If that fails, format may attempt a similar deduction on the riskier assumption that the destination was at column zero when format was invoked. If even this heuristic fails or is implementationally inconvenient, at worst the ~T operation will simply output two spaces.

~@T performs relative tabulation. ~colrel, colinc@T outputs colrel spaces and then outputs the smallest non-negative number of additional spaces necessary to move the cursor to a column that is a multiple of colinc. For example, the directive ~3,8@T outputs three spaces and then moves the cursor to a "standard multiple-of-eight tab stop" if not at one already. If the current output column cannot be determined, however, then colinc is ignored, and exactly colrel spaces are output.

If the *colon* modifier is used with the \sim T directive, the tabbing computation is done relative to the horizontal position where the section immediately containing the directive begins, rather than with respect to a horizontal position of zero. The numerical parameters are both interpreted as being in units of *ems* and both default to 1. $\sim n, m$:T is the same as (pprint-tab :section n m). $\sim n, m$:QT is the same as (pprint-tab :section-relative n m).

22.3.6.2 Tilde Less-Than-Sign: Justification

~mincol, colinc, minpad, padchar<str~>

This justifies the text produced by processing str within a field at least mincol columns wide. str may be divided up into segments with \sim ;, in which case the spacing is evenly divided between the text segments.

With no modifiers, the leftmost text segment is left justified in the field, and the rightmost text segment is right justified. If there is only one text element, as a special case, it is right justified. The : modifier causes spacing to be introduced before the first text segment; the $\mathfrak Q$ modifier causes spacing to be added after the last. The minpad parameter (default $\mathfrak Q$) is the minimum number of padding characters to be output between each segment. The padding character is supplied by padchar, which defaults to the space character. If the total width needed to satisfy these constraints is greater than mincol, then the width used is mincol+k*colinc for the smallest possible non-negative integer value k. colinc defaults to $\mathfrak Q$, and mincol defaults to $\mathfrak Q$.

Note that str may include format directives. All the clauses in str are processed in order; it is the resulting pieces of text that are justified.

The ~^ directive may be used to terminate processing of the clauses prematurely, in which case only the completely processed clauses are justified.

If the first clause of a \sim is terminated with \sim :; instead of \sim ;, then it is used in a special way. All of the clauses are processed (subject to \sim , of course), but the first one is not used in performing the spacing and padding. When the padded result has been determined, then if it will fit on the current line of output, it is output, and the text for the first clause is discarded. If, however, the padded text will not fit on the current line, then the text segment for the first clause is output before the padded text. The first clause ought to contain a newline (such as a \sim % directive). The first clause is always processed, and so any arguments it refers to will be used; the decision is whether to use the resulting segment of text, not whether to process the first clause. If the \sim :; has a prefix parameter n, then the padded text must fit on the current line with n character positions to spare to avoid outputting the first clause's text. For example, the control string

```
"~%;; ~{~<~%;; ~1:; ~S~>~^,~}.~%"
```

can be used to print a list of items separated by commas without breaking items over line boundaries, beginning each line with;; The prefix parameter 1 in ~1:; accounts for the width of the comma that will follow the justified item if it is not the last element in the list, or the period if it is. If ~:; has a second prefix parameter, then it is used as the width of the line, thus overriding the natural line width of the output stream. To make the preceding example use a line width of 50, one would write

If the second argument is not supplied, then **format** uses the line width of the *destination* output stream. If this cannot be determined (for example, when producing a *string* result), then **format** uses 72 as the line length.

See also Section 22.3.5.2 (Tilde Less-Than-Sign: Logical Block).

22.3.6.3 Tilde Greater-Than-Sign: End of Justification

~> terminates a ~<. The consequences of using it elsewhere are undefined.

22.3.7 FORMAT Control-Flow Operations

22.3.7.1 Tilde Asterisk: Go-To

The next arg is ignored. $\sim n*$ ignores the next n arguments.

 $\sim:*$ backs up in the list of arguments so that the argument last processed will be processed again. $\sim n:*$ backs up n arguments.

When within a ~{ construct (see below), the ignoring (in either direction) is relative to the list of arguments being processed by the iteration.

~n@* goes to the nth arg, where 0 means the first one; n defaults to 0, so ~@* goes back to the first arg. Directives after a ~n@* will take arguments in sequence beginning with the one gone to. When within a ~ $\{$ construct, the "goto" is relative to the list of arguments being processed by the iteration.

22.3.7.2 Tilde Left-Bracket: Conditional Expression

```
\sim [str0 \sim ; str1 \sim ; ... \sim ; strn \sim]
```

This is a set of control strings, called *clauses*, one of which is chosen and used. The clauses are separated by ~; and the construct is terminated by ~]. For example,

```
"~[Siamese~;Manx~;Persian~] Cat"
```

The argth clause is selected, where the first clause is number 0. If a prefix parameter is given (as $\sim n$ [), then the parameter is used instead of an argument. If arg is out of range then no clause is selected and no error is signaled. After the selected alternative has been processed, the control string continues after the \sim 1.

 $\sim [str0\sim; str1\sim; ...\sim; strn\sim:; default\sim]$ has a default case. If the last \sim ; used to separate clauses is $\sim:$; instead, then the last clause is an else clause that is performed if no other clause is selected. For example:

```
"~[Siamese~;Manx~;Persian~:;Alley~] Cat"
```

- ~:[alternative~;consequent~] selects the alternative control string if arg is false, and selects the consequent control string otherwise.
- ~@[consequent~] tests the argument. If it is true, then the argument is not used up by the ~[command but remains as the next one to be processed, and the one clause consequent is processed. If the arg is false, then the argument is used up, and the clause is not processed. The clause therefore should normally use exactly one argument, and may expect it to be non-nil. For example:

The combination of $\sim [$ and # is useful, for example, for dealing with English conventions for printing lists:

```
(setq foo "Items:~#[ none~; ~S~; ~S and ~S~
~:;~@{~#[~; and~] ~S~^,~}~].")
```

```
(format nil foo) \rightarrow "Items: none."

(format nil foo 'foo) \rightarrow "Items: FOO."

(format nil foo 'foo 'bar) \rightarrow "Items: FOO and BAR."

(format nil foo 'foo 'bar 'baz) \rightarrow "Items: FOO, BAR, and BAZ."

(format nil foo 'foo 'bar 'baz 'quux) \rightarrow "Items: FOO, BAR, BAZ, and QUUX."
```

22.3.7.3 Tilde Right-Bracket: End of Conditional Expression

~] terminates a ~[. The consequences of using it elsewhere are undefined.

22.3.7.4 Tilde Left-Brace: Iteration

```
~{str~}
```

This is an iteration construct. The argument should be a *list*, which is used as a set of arguments as if for a recursive call to **format**. The *string str* is used repeatedly as the control string. Each iteration can absorb as many elements of the *list* as it likes as arguments; if str uses up two arguments by itself, then two elements of the *list* will get used up each time around the loop. If before any iteration step the *list* is empty, then the iteration is terminated. Also, if a prefix parameter n is given, then there will be at most n repetitions of processing of str. Finally, the " directive can be used to terminate the iteration prematurely.

For example:

 \sim :{ $str\sim$ } is similar, but the argument should be a *list* of sublists. At each repetition step, one sublist is used as the set of arguments for processing str; on the next repetition, a new sublist is used, whether or not all of the last sublist had been processed. For example:

 $-0{str}$ is similar to $-{str}$, but instead of using one argument that is a list, all the remaining arguments are used as the list of arguments for the iteration. Example:

```
(format nil "Pairs:~\mathbb{Q}\{ <\infty, \sim \." 'a 1 'b 2 'c 3) \rightarrow "Pairs: <A,1> <B,2> <C,3>."
```

If the iteration is terminated before all the remaining arguments are consumed, then any arguments not processed by the iteration remain to be processed by any directives following the iteration construct.

~:@ $\{str~\}$ combines the features of ~: $\{str~\}$ and ~@ $\{str~\}$. All the remaining arguments are used, and each one must be a *list*. On each iteration, the next argument is used as a *list* of arguments to str. Example:

Terminating the repetition construct with ~:} instead of ~} forces str to be processed at least once, even if the initial list of arguments is null. However, this will not override an explicit prefix parameter of zero.

If str is empty, then an argument is used as str. It must be a format control and precede any arguments processed by the iteration. As an example, the following are equivalent:

```
(apply #'format stream string arguments)

= (format stream "~1{~:}" string arguments)
```

This will use string as a formatting string. The ~1{ says it will be processed at most once, and the ~:} says it will be processed at least once. Therefore it is processed exactly once, using arguments as the arguments. This case may be handled more clearly by the ~? directive, but this general feature of ~{ is more powerful than ~?.

22.3.7.5 Tilde Right-Brace: End of Iteration

~} terminates a ~{. The consequences of using it elsewhere are undefined.

22.3.7.6 Tilde Question-Mark: Recursive Processing

The next arg must be a format control, and the one after it a list; both are consumed by the ~? directive. The two are processed as a control-string, with the elements of the list as the arguments. Once the recursive processing has been finished, the processing of the control string containing the ~? directive is resumed. Example:

```
(format nil "~? ~D" "<~A ~D>" '("Foo" 5) 7) \rightarrow "<Foo 5> 7" (format nil "~? ~D" "<~A ~D>" '("Foo" 5 14) 7) \rightarrow "<Foo 5> 7"
```

Note that in the second example three arguments are supplied to the *format string* " $<\sim A$ ~D>", but only two are processed and the third is therefore ignored.

With the @ modifier, only one arg is directly consumed. The arg must be a string; it is processed as part of the control string as if it had appeared in place of the ~@? construct, and any directives in the recursively processed control string may consume arguments of the control string containing the ~@? directive. Example:

```
(format nil "~@? ~D" "<~A ~D>" "Foo" 5 7) \rightarrow "<Foo 5> 7" (format nil "~@? ~D" "<~A ~D>" "Foo" 5 14 7) \rightarrow "<Foo 5> 14"
```

22.3.8 FORMAT Miscellaneous Operations

22.3.8.1 Tilde Left-Paren: Case Conversion

```
~(str~)
```

The contained control string str is processed, and what it produces is subject to case conversion.

With no flags, every uppercase character is converted to the corresponding lowercase character.

- ~: (capitalizes all words, as if by string-capitalize.
- ~@(capitalizes just the first word and forces the rest to lower case.
- $\sim: @($ converts every lower case character to the corresponding uppercase character.

In this example ~@(is used to cause the first word produced by ~@R to be capitalized:

```
(format nil "~QR ~(~QR~)" 14 14) 

\rightarrow "XIV xiv" 

(defun f (n) (format nil "~Q(~R~) error~:P detected." n)) \rightarrow F 

(f 0) \rightarrow "Zero errors detected." 

(f 1) \rightarrow "One error detected." 

(f 23) \rightarrow "Twenty-three errors detected."
```

When case conversions appear nested, the outer conversion dominates, as illustrated in the following example:

```
(format nil "~@(how is ~:(BOB SMITH~)?~)") \to "How is bob smith?" \to "How is Bob Smith?"
```

22.3.8.2 Tilde Right-Paren: End of Case Conversion

~) terminates a ~(. The consequences of using it elsewhere are undefined.

22.3.8.3 Tilde P: Plural

If arg is not eql to the integer 1, a lowercase s is printed; if arg is eql to 1, nothing is printed. If arg is a floating-point 1.0, the s is printed.

~:P does the same thing, after doing a ~:* to back up one argument; that is, it prints a lowercase s if the previous argument was not 1.

~@P prints y if the argument is 1, or ies if it is not. ~: @P does the same thing, but backs up first.

```
(format nil "~D tr~:@P/~D win~:P" 7 1) \to "7 tries/1 win" (format nil "~D tr~:@P/~D win~:P" 1 0) \to "1 try/0 wins"
```

```
(format nil "~D tr~:@P/~D win~:P" 1 3) \rightarrow "1 try/3 wins"
```

22.3.9 FORMAT Miscellaneous Pseudo-Operations

22.3.9.1 Tilde Semicolon: Clause Separator

This separates clauses in \sim [and \sim constructs. The consequences of using it elsewhere are undefined.

22.3.9.2 Tilde Circumflex: Escape Upward

~ ^

This is an escape construct. If there are no more arguments remaining to be processed, then the immediately enclosing ~{ or ~< construct is terminated. If there is no such enclosing construct, then the entire formatting operation is terminated. In the ~< case, the formatting is performed, but no more segments are processed before doing the justification. ~^ may appear anywhere in a ~{ construct.}

```
(setq donestr "Done.~^ ~D warning~:P.~^ ~D error~:P.") \rightarrow "Done.~^ ~D warning~:P.~^ ~D error~:P." (format nil donestr) \rightarrow "Done." (format nil donestr 3) \rightarrow "Done. 3 warnings." (format nil donestr 1 5) \rightarrow "Done. 1 warning. 5 errors."
```

If a prefix parameter is given, then termination occurs if the parameter is zero. (Hence \sim is equivalent to \sim # \sim .) If two parameters are given, termination occurs if they are equal. If three parameters are given, termination occurs if the first is less than or equal to the second and the second is less than or equal to the third. Of course, this is useless if all the prefix parameters are constants; at least one of them should be a # or a V parameter.

If ~^ is used within a ~:{ construct, then it terminates the current iteration step because in the standard case it tests for remaining arguments of the current step only; the next iteration step commences immediately. ~:^ is used to terminate the iteration process. ~:^ may be used only if the command it would terminate is ~:{ or ~:@{. The entire iteration process is terminated if and only if the sublist that is supplying the arguments for the current iteration step is the last sublist in the case of ~:@{. ~:^ is not equivalent to ~#:^; the latter terminates the entire iteration if and only if no arguments remain for the current iteration step. For example:

```
(format nil "~:{~@?~:^...~}" '(("a") ("b"))) \rightarrow "a...b"
```

If ~^ appears within a control string being processed under the control of a ~? directive, but not within any ~{ or ~< construct within that string, then the string being processed will be terminated, thereby ending processing of the ~? directive. Processing then continues within the string containing the ~? directive at the point following that directive.

If ~^ appears within a ~[or ~(construct, then all the commands up to the ~^ are properly selected or case-converted, the ~[or ~(processing is terminated, and the outward search continues for a ~{ or ~< construct to be terminated. For example:

22.3.9.3 Tilde Newline: Ignored Newline

Tilde immediately followed by a newline ignores the newline and any following non-newline whitespace₁ characters. With a :, the newline is ignored, but any following whitespace₁ is left in place. With an \mathfrak{C} , the newline is left in place, but any following whitespace₁ is ignored. For example:

Note that in this example newlines appear in the output only as specified by the ~& and ~% directives; the actual newline characters in the control string are suppressed because each is preceded by a tilde.

22.3.10 Additional Information about FORMAT Operations

22.3.10.1 Nesting of FORMAT Operations

The case-conversion, conditional, iteration, and justification constructs can contain other formatting constructs by bracketing them. These constructs must nest properly with respect to each other. For example, it is not legitimate to put the start of a case-conversion construct in each arm of a conditional and the end of the case-conversion construct outside the conditional:

```
(format nil "~:[abc~:@(def~;ghi~
:@(jkl~]mno~)" x) ;Invalid!
```

This notation is invalid because the $\sim [\ldots \sim]$ and $\sim (\ldots \sim)$ constructs are not properly nested.

The processing indirection caused by the ~? directive is also a kind of nesting for the purposes of this rule of proper nesting. It is not permitted to start a bracketing construct within a string processed under control of a ~? directive and end the construct at some point after the ~? construct in the string containing that construct, or vice versa. For example, this situation is invalid:

```
(format nil "~0?ghi~)" "abc~0(def"); Invalid!
```

This notation is invalid because the ~? and ~(...~) constructs are not properly nested.

22.3.10.2 Missing and Additional FORMAT Arguments

The consequences are undefined if no *arg* remains for a directive requiring an argument. However, it is permissible for one or more *args* to remain unprocessed by a directive; such *args* are ignored.

22.3.10.3 Additional FORMAT Parameters

The consequences are undefined if a format directive is given more parameters than it is described here as accepting.

22.3.10.4 Undefined FORMAT Modifier Combinations

The consequences are undefined if *colon* or *at-sign* modifiers are given to a directive in a combination not specifically described here as being meaningful.

22.3.11 Examples of FORMAT

```
(format nil "foo") 
ightarrow "foo"
 (setq x 5) \rightarrow 5
 (format nil "The answer is ~D." x) 
ightarrow "The answer is 5."
 (format nil "The answer is ~3D." x) 
ightarrow "The answer is
 (format nil "The answer is ~3, 'OD." x) \rightarrow "The answer is 005."
 (format nil "The answer is ~:D." (expt 47 x))
\rightarrow "The answer is 229,345,007."
 (setq y "elephant") 	o "elephant"
 (format nil "Look at the ~A!" y) \rightarrow "Look at the elephant!"
 (setq n 3) \rightarrow 3
 (format nil "~D item~:P found." n) \rightarrow "3 items found."
 (format nil "~R dog~:[s are~; is~] here." n (= n 1))

ightarrow "three dogs are here."
(format nil "~R dog~:*~[s are~; is~:;s are~] here." n)

ightarrow "three dogs are here."
(format nil "Here ~[are~;is~:;are~] ~:*~R pupp~:@P." n)

ightarrow "Here are three puppies."
 (defun foo (x)
   (format nil "^{6},2F|^{6},2,1,^{4}F|^{6},2,^{2}F|^{6}F|^{7}F|^{8}
           x x x x x x x)) \rightarrow F00
 (foo 3.14159) \rightarrow " 3.14| 31.42| 3.14|3.1416|3.14|3.14159"
 (foo -3.14159) \rightarrow "-3.14|-31.42|-3.14|-3.142|-3.14|-3.14159"
 (foo 100.0) \rightarrow "100.00|*****|100.00| 100.0|100.00|100.0"

  (FORMAT NIL "Written to ~A." #P"foo.bin")

ightarrow "Written to foo.bin."
```

22.3.12 Notes about FORMAT

Formatted output is performed not only by **format**, but by certain other functions that accept a format control the way **format** does. For example, error-signaling functions such as **cerror** accept format controls.

Note that the meaning of nil and t as destinations to format are different than those of nil and t as $stream\ designators$.

The ~^ should appear only at the beginning of a ~< clause, because it aborts the entire clause in which it appears (as well as all following clauses).

copy-pprint-dispatch

Function

Syntax:

copy-pprint-dispatch &optional table ightarrow new-table

Arguments and Values:

 $\textit{table}\text{---} a \ pprint \ dispatch \ table, or \ \mathbf{nil}.$

new-table—a fresh pprint dispatch table.

Description:

Creates and returns a copy of the specified *table*, or of the *value* of ***print-pprint-dispatch*** if no *table* is specified, or of the initial *value* of ***print-pprint-dispatch*** if **nil** is specified.

Exceptional Situations:

Should signal an error of type type-error if table is not a pprint dispatch table.

formatter

Syntax:

 $formatter control\text{-string} \rightarrow function$

Arguments and Values:

control-string—a format string; not evaluated.

function—a function.

Description:

Returns a function which has behavior equivalent to:

```
#'(lambda (*standard-output* &rest arguments)
     (apply #'format t control-string arguments)
     arguments-tail)
```

where arguments-tail is either the tail of arguments which has as its car the argument that would be processed next if there were more format directives in the control-string, or else nil if no more arguments follow the most recently processed argument.

Examples:

```
(funcall (formatter "~&~A~A") *standard-output* 'a 'b 'c) \rhd AB \to (C)
```

```
(format t (formatter "~&~A~A") 'a 'b 'c) \rhd AB \rightarrow NIL
```

Exceptional Situations:

Might signal an error (at macro expansion time or at run time) if the argument is not a valid format string.

See Also:

format

pprint-dispatch

Function

Syntax:

pprint-dispatch object & optional table \rightarrow function, found-p

Arguments and Values:

object—an object.

table—a pprint dispatch table, or nil. The default is the value of *print-pprint-dispatch*.

function—a function designator.

found-p—a generalized boolean.

Description:

Retrieves the highest priority function in *table* that is associated with a *type specifier* that matches *object*. The function is chosen by finding all of the *type specifiers* in *table* that match the *object* and selecting the highest priority function associated with any of these *type specifiers*. If there is more than one highest priority function, an arbitrary choice is made. If no *type specifiers* match the *object*, a function is returned that prints *object* using **print-object**.

The $secondary\ value$, found-p, is true if a matching $type\ specifier$ was found in table, or false otherwise.

If table is nil, retrieval is done in the initial pprint dispatch table.

Affected By:

The state of the table.

Exceptional Situations:

Should signal an error of type type-error if table is neither a pprint-dispatch-table nor nil.

Notes:

pprint-exit-if-list-exhausted

Local Macro

Syntax:

pprint-exit-if-list-exhausted $\langle no \ arguments \rangle \rightarrow nil$

Description:

Tests whether or not the *list* passed to the *lexically current logical block* has been exhausted; see Section 22.2.1.1 (Dynamic Control of the Arrangement of Output). If this *list* has been reduced to nil, pprint-exit-if-list-exhausted terminates the execution of the *lexically current logical block* except for the printing of the suffix. Otherwise pprint-exit-if-list-exhausted returns nil.

Whether or not **pprint-exit-if-list-exhausted** is *fbound* in the *global environment* is *implementation-dependent*; however, the restrictions on redefinition and *shadowing* of **pprint-exit-if-list-exhausted** are the same as for *symbols* in the COMMON-LISP *package* which are *fbound* in the *global environment*. The consequences of attempting to use **pprint-exit-if-list-exhausted** outside of **pprint-logical-block** are undefined.

Exceptional Situations:

An error is signaled (at macro expansion time or at run time) if **pprint-exit-if-list-exhausted** is used anywhere other than lexically within a call on **pprint-logical-block**. Also, the consequences of executing **pprint-if-list-exhausted** outside of the dynamic extent of the **pprint-logical-block** which lexically contains it are undefined.

See Also:

pprint-logical-block, pprint-pop.

pprint-fill, pprint-linear, pprint-tabular

pprint-fill, pprint-linear, pprint-tabular

Function

Syntax:

```
pprint-fill stream object & optional colon-p at-sign-p \rightarrow nil pprint-linear stream object & optional colon-p at-sign-p \rightarrow nil pprint-tabular stream object & optional colon-p at-sign-p tabsize \rightarrow nil
```

Arguments and Values:

```
stream—an output stream designator.

object—an object.

colon-p—a generalized boolean. The default is true.

at-sign-p—a generalized boolean. The default is implementation-dependent.

tabsize—a non-negative integer. The default is 16.
```

Description:

The functions **pprint-fill**, **pprint-linear**, and **pprint-tabular** specify particular ways of *pretty* printing a list to stream. Each function prints parentheses around the output if and only if colon-p is true. Each function ignores its at-sign-p argument. (Both arguments are included even though only one is needed so that these functions can be used via ~/.../ and as **set-pprint-dispatch** functions, as well as directly.) Each function handles abbreviation and the detection of circularity and sharing correctly, and uses **write** to print object when it is a non-list.

If object is a list and if the value of *print-pretty* is false, each of these functions prints object using a minimum of whitespace, as described in Section 22.1.3.5 (Printing Lists and Conses). Otherwise (if object is a list and if the value of *print-pretty* is true):

- The function **pprint-linear** prints a list either all on one line, or with each element on a separate line.
- The function pprint-fill prints a list with as many elements as possible on each line.
- The function **pprint-tabular** is the same as **pprint-fill** except that it prints the elements so that they line up in columns. The **tabsize** specifies the column spacing in ems, which is the total spacing from the leading edge of one column to the leading edge of the next.

Examples:

Evaluating the following with a line length of 25 produces the output shown.

```
(progn (princ "Roads ")
```

Side Effects:

Performs output to the indicated stream.

Affected By:

The cursor position on the indicated *stream*, if it can be determined.

Notes:

The function **pprint-tabular** could be defined as follows:

Note that it would have been inconvenient to specify this function using **format**, because of the need to pass its *tabsize* argument through to a ~:T format directive nested within an iteration over a list.

pprint-indent

Function

Syntax:

pprint-indent relative-to n & optional stream \rightarrow nil

Arguments and Values:

```
relative-to—either :block or :current.
n—a real.
```

stream—an output stream designator. The default is standard output.

Description:

pprint-indent specifies the indentation to use in a logical block on *stream*. If *stream* is a *pretty printing stream* and the *value* of *print-pretty* is *true*, **pprint-indent** sets the indentation in the innermost dynamically enclosing logical block; otherwise, **pprint-indent** has no effect.

N specifies the indentation in ems. If relative-to is :block, the indentation is set to the horizontal position of the first character in the dynamically current logical block plus n ems. If relative-to is :current, the indentation is set to the current output position plus n ems. (For robustness in the face of variable-width fonts, it is advisable to use :current with an n of zero whenever possible.)

N can be negative; however, the total indentation cannot be moved left of the beginning of the line or left of the end of the rightmost per-line prefix—an attempt to move beyond one of these limits is treated the same as an attempt to move to that limit. Changes in indentation caused by *pprint-indent* do not take effect until after the next line break. In addition, in miser mode all calls to **pprint-indent** are ignored, forcing the lines corresponding to the logical block to line up under the first character in the block.

Exceptional Situations:

An error is signaled if *relative-to* is any *object* other than :block or :current.

See Also:

Section 22.3.5.3 (Tilde I: Indent)

pprint-logical-block

Macro

Syntax:

```
 \begin{array}{l} \textbf{pprint-logical-block} \ (\textit{stream-symbol object \&key prefix per-line-prefix suffix}) \\ \{\textit{declaration}\}^* \ \{\textit{form}\}^* \end{array}
```

ightarrow nil ${\bf Arguments \ and \ Values:}$

```
stream-symbol—a stream variable designator.

object—an object; evaluated.
```

:prefix—a string; evaluated. Complicated defaulting behavior; see below.

:per-line-prefix—a string; evaluated. Complicated defaulting behavior; see below.

:suffix—a string; evaluated. The default is the null string.

declaration—a declare expression; not evaluated.

forms—an implicit progn.

pprint-logical-block

Description:

Causes printing to be grouped into a logical block.

The logical block is printed to the *stream* that is the *value* of the *variable* denoted by *stream-symbol*. During the execution of the *forms*, that *variable* is *bound* to a *pretty printing stream* that supports decisions about the arrangement of output and then forwards the output to the destination stream. All the standard printing functions (*e.g.*, **write**, **princ**, and **terpri**) can be used to print output to the *pretty printing stream*. All and only the output sent to this *pretty printing stream* is treated as being in the logical block.

The *prefix* specifies a prefix to be printed before the beginning of the logical block. The *per-line-prefix* specifies a prefix that is printed before the block and at the beginning of each new line in the block. The :prefix and :pre-line-prefix arguments are mutually exclusive. If neither :prefix nor :per-line-prefix is specified, a *prefix* of the *null string* is assumed.

The *suffix* specifies a suffix that is printed just after the logical block.

The *object* is normally a *list* that the body *forms* are responsible for printing. If *object* is not a *list*, it is printed using **write**. (This makes it easier to write printing functions that are robust in the face of malformed arguments.) If *print-circle* is *non-nil* and *object* is a circular (or shared) reference to a *cons*, then an appropriate "#n#" marker is printed. (This makes it easy to write printing functions that provide full support for circularity and sharing abbreviation.) If *print-level* is not nil and the logical block is at a dynamic nesting depth of greater than *print-level* in logical blocks, "#" is printed. (This makes easy to write printing functions that provide full support for depth abbreviation.)

If either of the three conditions above occurs, the indicated output is printed on *stream-symbol* and the body *forms* are skipped along with the printing of the :prefix and :suffix. (If the body *forms* are not to be responsible for printing a list, then the first two tests above can be turned off by supplying nil for the *object* argument.)

In addition to the *object* argument of **pprint-logical-block**, the arguments of the standard printing functions (such as **write**, **print**, **prin1**, and **pprint**, as well as the arguments of the standard *format directives* such as ~A, ~S, (and ~W) are all checked (when necessary) for circularity and sharing. However, such checking is not applied to the arguments of the functions **write-line**, **write-string**, and **write-char** or to the literal text output by **format**. A consequence of this is that you must use one of the latter functions if you want to print some literal text in the output that is not supposed to be checked for circularity or sharing.

The body forms of a **pprint-logical-block** form must not perform any side-effects on the surrounding environment; for example, no variables must be assigned which have not been bound within its scope.

The **pprint-logical-block** macro may be used regardless of the value of *print-pretty*.

Affected By:

print-circle, *print-level*.

Exceptional Situations:

An error of type type-error is signaled if any of the :suffix, :prefix, or :per-line-prefix is supplied but does not evaluate to a string.

An error is signaled if :prefix and :pre-line-prefix are both used.

pprint-logical-block and the *pretty printing stream* it creates have *dynamic extent*. The consequences are undefined if, outside of this extent, output is attempted to the *pretty printing stream* it creates.

It is also unspecified what happens if, within this extent, any output is sent directly to the underlying destination stream.

See Also:

pprint-pop, pprint-exit-if-list-exhausted, Section 22.3.5.2 (Tilde Less-Than-Sign: Logical Block)

Notes:

One reason for using the **pprint-logical-block** macro when the value of ***print-pretty*** is **nil** would be to allow it to perform checking for dotted lists, as well as (in conjunction with **pprint-pop**) checking for ***print-level*** or ***print-length*** being exceeded.

Detection of circularity and sharing is supported by the *pretty printer* by in essence performing requested output twice. On the first pass, circularities and sharing are detected and the actual outputting of characters is suppressed. On the second pass, the appropriate "#n=" and "#n#" markers are inserted and characters are output. This is why the restriction on side-effects is necessary. Obeying this restriction is facilitated by using **pprint-pop**, instead of an ordinary **pop** when traversing a list being printed by the body *forms* of the **pprint-logical-block** *form*.)

pprint-newline

Function

Syntax:

pprint-newline kind &optional stream ightarrow ightarrow ightarrow ightarrow ightarrow ightarrow

Arguments and Values:

kind—one of :linear, :fill, :miser, or :mandatory.

stream—a stream designator. The default is standard output.

Description:

If stream is a pretty printing stream and the value of *print-pretty* is true, a line break is inserted in the output when the appropriate condition below is satisfied; otherwise, pprint-newline has no effect.

Kind specifies the style of conditional newline. This parameter is treated as follows:

pprint-newline

:linear

This specifies a "linear-style" *conditional newline*. A line break is inserted if and only if the immediately containing *section* cannot be printed on one line. The effect of this is that line breaks are either inserted at every linear-style conditional newline in a logical block or at none of them.

:miser

This specifies a "miser-style" conditional newline. A line break is inserted if and only if the immediately containing section cannot be printed on one line and miser style is in effect in the immediately containing logical block. The effect of this is that miser-style conditional newlines act like linear-style conditional newlines, but only when miser style is in effect. Miser style is in effect for a logical block if and only if the starting position of the logical block is less than or equal to *print-miser-width* ems from the right margin.

:fill

This specifies a "fill-style" conditional newline. A line break is inserted if and only if either (a) the following section cannot be printed on the end of the current line, (b) the preceding section was not printed on a single line, or (c) the immediately containing section cannot be printed on one line and miser style is in effect in the immediately containing logical block. If a logical block is broken up into a number of subsections by fill-style conditional newlines, the basic effect is that the logical block is printed with as many subsections as possible on each line. However, if miser style is in effect, fill-style conditional newlines act like linear-style conditional newlines.

:mandatory

This specifies a "mandatory-style" *conditional newline*. A line break is always inserted. This implies that none of the containing *sections* can be printed on a single line and will therefore trigger the insertion of line breaks at linear-style conditional newlines in these *sections*.

When a line break is inserted by any type of conditional newline, any blanks that immediately precede the conditional newline are omitted from the output and indentation is introduced at the beginning of the next line. By default, the indentation causes the following line to begin in the same horizontal position as the first character in the immediately containing logical block. (The indentation can be changed via **pprint-indent**.)

There are a variety of ways unconditional newlines can be introduced into the output (*i.e.*, via **terpri** or by printing a string containing a newline character). As with mandatory conditional newlines, this prevents any of the containing *sections* from being printed on one line. In general, when an unconditional newline is encountered, it is printed out without suppression of the preceding blanks and without any indentation following it. However, if a per-line prefix has been specified (see **pprint-logical-block**), this prefix will always be printed no matter how a newline originates.

Examples:

See Section 22.2.2 (Examples of using the Pretty Printer).

Side Effects:

Output to stream.

Affected By:

print-pretty, *print-miser*. The presence of containing logical blocks. The placement of newlines and conditional newlines.

Exceptional Situations:

An error of type type-error is signaled if kind is not one of :linear, :fill, :miser, or :mandatory.

See Also:

Section 22.3.5.1 (Tilde Underscore: Conditional Newline), Section 22.2.2 (Examples of using the Pretty Printer)

pprint-pop

Local Macro

Syntax:

pprint-pop $\langle no \ arguments \rangle \rightarrow object$

Arguments and Values:

object—an element of the list being printed in the lexically current logical block, or nil.

Description:

Pops one *element* from the *list* being printed in the *lexically current logical block*, obeying *print-length* and *print-circle* as described below.

Each time **pprint-pop** is called, it pops the next value off the *list* passed to the *lexically current* logical block and returns it. However, before doing this, it performs three tests:

- If the remaining 'list' is not a *list*, ". " is printed followed by the remaining 'list.' (This makes it easier to write printing functions that are robust in the face of malformed arguments.)
- If *print-length* is non-nil, and pprint-pop has already been called *print-length* times within the immediately containing logical block, "..." is printed. (This makes it easy to write printing functions that properly handle *print-length*.)

• If *print-circle* is non-nil, and the remaining list is a circular (or shared) reference, then ". " is printed followed by an appropriate "#n#" marker. (This catches instances of cdr circularity and sharing in lists.)

If either of the three conditions above occurs, the indicated output is printed on the *pretty printing* stream created by the immediately containing **pprint-logical-block** and the execution of the immediately containing **pprint-logical-block** is terminated except for the printing of the suffix.

If **pprint-logical-block** is given a 'list' argument of **nil**—because it is not processing a list—**pprint-pop** can still be used to obtain support for ***print-length***. In this situation, the first and third tests above are disabled and **pprint-pop** always returns **nil**. See Section 22.2.2 (Examples of using the Pretty Printer)—specifically, the **pprint-vector** example.

Whether or not **pprint-pop** is *fbound* in the *global environment* is *implementation-dependent*; however, the restrictions on redefinition and *shadowing* of **pprint-pop** are the same as for *symbols* in the COMMON-LISP *package* which are *fbound* in the *global environment*. The consequences of attempting to use **pprint-pop** outside of **pprint-logical-block** are undefined.

Side Effects:

Might cause output to the pretty printing stream associated with the lexically current logical block.

Affected By:

print-length, *print-circle*.

Exceptional Situations:

An error is signaled (either at macro expansion time or at run time) if a usage of **pprint-pop** occurs where there is no lexically containing **pprint-logical-block** form.

The consequences are undefined if **pprint-pop** is executed outside of the *dynamic extent* of this **pprint-logical-block**.

See Also:

pprint-exit-if-list-exhausted, pprint-logical-block.

Notes:

It is frequently a good idea to call **pprint-exit-if-list-exhausted** before calling **pprint-pop**.

pprint-tab

Function

Syntax:

pprint-tab kind colnum colinc & optional stream \rightarrow nil

Arguments and Values:

```
kind—one of :line, :section, :line-relative, or :section-relative.
colnum—a non-negative integer.
colinc—a non-negative integer.
stream—an output stream designator.
```

Description:

Specifies tabbing to *stream* as performed by the standard ~T format directive. If *stream* is a *pretty printing stream* and the *value* of *print-pretty* is *true*, tabbing is performed; otherwise, pprint-tab has no effect.

The arguments colnum and colinc correspond to the two parameters to ~T and are in terms of ems. The kind argument specifies the style of tabbing. It must be one of :line (tab as by ~T), :section (tab as by ~:T, but measuring horizontal positions relative to the start of the dynamically enclosing section), :line-relative (tab as by ~@T), or :section-relative (tab as by ~:@T, but measuring horizontal positions relative to the start of the dynamically enclosing section).

Exceptional Situations:

An error is signaled if kind is not one of :line, :section, :line-relative, or :section-relative.

See Also:

pprint-logical-block

print-object

Standard Generic Function

Syntax:

```
print-object object stream \rightarrow object
```

Method Signatures:

```
print-object (object standard-object) stream
print-object (object structure-object) stream
```

Arguments and Values:

```
object—an object.
stream—a stream.
```

print-object

Description:

The generic function **print-object** writes the printed representation of **object** to **stream**. The function **print-object** is called by the Lisp printer; it should not be called by the user.

Each implementation is required to provide a *method* on the *class* **standard-object** and on the *class* **structure-object**. In addition, each *implementation* must provide *methods* on enough other *classes* so as to ensure that there is always an applicable *method*. Implementations are free to add *methods* for other *classes*. Users may write *methods* for **print-object** for their own *classes* if they do not wish to inherit an *implementation-dependent method*.

The *method* on the *class* **structure-object** prints the object in the default **#S** notation; see Section 22.1.3.12 (Printing Structures).

Methods on **print-object** are responsible for implementing their part of the semantics of the printer control variables, as follows:

print-readably

All methods for **print-object** must obey ***print-readably***. This includes both user-defined methods and *implementation-defined* methods. Readable printing of *structures* and *standard objects* is controlled by their **print-object** method, not by their **make-load-form** *method*. Similarity for these *objects* is application dependent and hence is defined to be whatever these *methods* do; see Section 3.2.4.2 (Similarity of Literal Objects).

print-escape

Each method must implement *print-escape*.

print-pretty

The *method* may wish to perform specialized line breaking or other output conditional on the *value* of *print-pretty*. For further information, see (for example) the *macro* pprint-fill. See also Section 22.2.1.4 (Pretty Print Dispatch Tables) and Section 22.2.2 (Examples of using the Pretty Printer).

print-length

Methods that produce output of indefinite length must obey *print-length*. For further information, see (for example) the macros pprint-logical-block and pprint-pop. See also Section 22.2.1.4 (Pretty Print Dispatch Tables) and Section 22.2.2 (Examples of using the Pretty Printer).

print-level

The printer takes care of *print-level* automatically, provided that each method handles exactly one level of structure and calls write (or an equivalent function) recursively if there are more structural levels. The printer's decision of whether an object has components (and

therefore should not be printed when the printing depth is not less than *print-level*) is implementation-dependent. In some implementations its print-object method is not called; in others the method is called, and the determination that the object has components is based on what it tries to write to the stream.

print-circle

When the value of *print-circle* is true, a user-defined print-object method can print objects to the supplied stream using write, prin1, princ, or format and expect circularities to be detected and printed using the #n# syntax. If a user-defined print-object method prints to a stream other than the one that was supplied, then circularity detection starts over for that stream. See *print-circle*.

print-base, *print-radix*, *print-case*, *print-gensym*, and *print-array*

These printer control variables apply to specific types of objects and are handled by the methods for those objects.

If these rules are not obeyed, the results are undefined.

In general, the printer and the **print-object** methods should not rebind the print control variables as they operate recursively through the structure, but this is *implementation-dependent*.

In some implementations the *stream* argument passed to a **print-object** *method* is not the original *stream*, but is an intermediate *stream* that implements part of the printer. *methods* should therefore not depend on the identity of this *stream*.

pprint-fill, pprint-logical-block, pprint-pop, write, *print-readably*, *print-escape*, *print-pretty*, *print-length*, Section 22.1.3 (Default Print-Object Methods), Section 22.1.3.12 (Printing Structures), Section 22.2.1.4 (Pretty Print Dispatch Tables), Section 22.2.2 (Examples of using the Pretty Printer)

print-unreadable-object

Macro

Syntax:

print-unreadable-object (object stream &key type identity) $\{form\}^* \rightarrow nil$

Arguments and Values:

object—an object; evaluated.

stream—a stream designator; evaluated.

type—a generalized boolean; evaluated.

```
identity—a generalized boolean; evaluated.
```

forms—an implicit progn.

Description:

Outputs a printed representation of *object* on *stream*, beginning with "#<" and ending with ">". Everything output to *stream* by the body *forms* is enclosed in the the angle brackets. If *type* is *true*, the output from *forms* is preceded by a brief description of the *object*'s *type* and a space character. If *identity* is *true*, the output from *forms* is followed by a space character and a representation of the *object*'s identity, typically a storage address.

If either type or identity is not supplied, its value is false. It is valid to omit the body forms. If type and identity are both true and there are no body forms, only one space character separates the type and the identity.

Examples:

;; Note that in this example, the precise form of the output ;; is implementation-dependent.

Exceptional Situations:

If *print-readably* is true, print-unreadable-object signals an error of type print-not-readable without printing anything.

set-pprint-dispatch

Function

Syntax:

 $\operatorname{set-pprint-dispatch}$ type-specifier function & optional priority table ightarrow nil

Arguments and Values:

```
type-specifier—a type specifier.

function—a function, a function name, or nil.

priority—a real. The default is 0.

table—a pprint dispatch table. The default is the value of *print-pprint-dispatch*.
```

Description:

Installs an entry into the *pprint dispatch table* which is *table*.

Type-specifier is the key of the entry. The first action of **set-pprint-dispatch** is to remove any pre-existing entry associated with type-specifier. This guarantees that there will never be two entries associated with the same type specifier in a given pprint dispatch table. Equality of type specifiers is tested by **equal**.

Two values are associated with each type specifier in a pprint dispatch table: a function and a priority. The function must accept two arguments: the stream to which output is sent and the object to be printed. The function should pretty print the object to the stream. The function can assume that object satisfies the type given by type-specifier. The function must obey *print-readably*. Any values returned by the function are ignored.

Priority is a priority to resolve conflicts when an object matches more than one entry.

It is permissible for *function* to be **nil**. In this situation, there will be no *type-specifier* entry in *table* after **set-pprint-dispatch** returns.

Exceptional Situations:

An error is signaled if *priority* is not a *real*.

Notes:

Since pprint dispatch tables are often used to control the pretty printing of Lisp code, it is common for the type-specifier to be an expression of the form

```
(cons car-type cdr-type)
```

This signifies that the corresponding object must be a cons cell whose *car* matches the *type specifier car-type* and whose *cdr* matches the *type specifier cdr-type*. The *cdr-type* can be omitted in which case it defaults to t.

write, prin1, print, print, princ

Function

Syntax:

write object &key array base case circle escape gensym length level lines miser-width pprint-dispatch pretty radix readably right-margin stream

```
\rightarrow object
```

```
prin1 object &optional output-stream → object
princ object &optional output-stream → object
```

write, prin1, print, print, princ

```
print object &optional output-stream \rightarrow object
           pprint object & optional output-stream \rightarrow \langle no \ values \rangle
Arguments and Values:
           object—an object.
           output-stream—an output stream designator. The default is standard output.
           array—a generalized boolean.
           base—a radix.
           case—a symbol of type (member :upcase :downcase :capitalize).
           circle—a generalized boolean.
           escape—a generalized boolean.
           gensym—a generalized boolean.
           length—a non-negative integer, or nil.
           level—a non-negative integer, or nil.
           lines—a non-negative integer, or nil.
           miser-width—a non-negative integer, or nil.
           pprint-dispatch—a pprint dispatch table.
           pretty—a generalized boolean.
           radix—a generalized boolean.
           readably—a generalized boolean.
           right-margin—a non-negative integer, or nil.
```

stream—an output stream designator. The default is standard output.

Description:

write, prin1, princ, print, and pprint write the printed representation of object to output-stream.

write is the general entry point to the *Lisp printer*. For each explicitly supplied *keyword parameter* named in Figure 22–7, the corresponding *printer control variable* is dynamically bound to its *value* while printing goes on; for each *keyword parameter* in Figure 22–7 that is not explicitly supplied, the value of the corresponding *printer control variable* is the same as it was at the time write was invoked. Once the appropriate *bindings* are *established*, the *object* is output by the *Lisp printer*.

write, prin1, print, print, princ

Parameter	Corresponding Dynamic Variable
array	*print-array*
base	*print-base*
case	*print-case*
circle	*print-circle*
escape	*print-escape*
gensym	*print-gensym*
length	*print-length*
level	*print-level*
lines	*print-lines*
miser-width	*print-miser-width*
pprint-dispatch	*print-pprint-dispatch*
pretty	*print-pretty*
radix	*print-radix*
readably	*print-readably*
right-margin	*print-right-margin*

Figure 22–7. Argument correspondences for the WRITE function.

prin1, princ, print, and pprint implicitly bind certain print parameters to particular values. The remaining parameter values are taken from *print-array*, *print-base*, *print-case*, *print-circle*, *print-escape*, *print-gensym*, *print-length*, *print-level*, *print-lines*, *print-miser-width*, *print-pprint-dispatch*, *print-pretty*, *print-radix*, and *print-right-margin*.

prin1 produces output suitable for input to read. It binds *print-escape* to true.

princ is just like **prin1** except that the output has no *escape characters*. It binds ***print-escape*** to *false* and ***print-readably*** to *false*. The general rule is that output from **princ** is intended to look good to people, while output from **prin1** is intended to be acceptable to **read**.

print is just like **prin1** except that the printed representation of *object* is preceded by a newline and followed by a space.

pprint is just like **print** except that the trailing space is omitted and *object* is printed with the ***print-pretty*** flag *non-nil* to produce pretty output.

Output-stream specifies the stream to which output is to be sent.

Affected By:

standard-output, *terminal-io*, *print-escape*, *print-radix*, *print-base*, *print-circle*, *print-pretty*, *print-level*, *print-length*, *print-case*, *print-gensym*, *print-array*, *read-default-float-format*.

See Also:

readtable-case, Section 22.3.4 (FORMAT Printer Operations)

The functions prin1 and print do not bind *print-readably*.

Notes:

```
(prin1 object output-stream)

\[ \equiv (write object :stream output-stream :escape t)

(princ object output-stream)

\[ (write object stream output-stream :escape nil :readably nil)

(print object output-stream)

\[ (print object output-stream)

\[ (write object :stream output-stream :escape t)
\]
```

(write-char #\space output-stream))

≡ (write object :stream output-stream :escape t :pretty t)

write-to-string, prin1-to-string, princ-to-string

Function

(pprint object output-stream)

Syntax:

```
write-to-string object &key array base case circle escape gensym
length level lines miser-width pprint-dispatch
pretty radix readably right-margin

→ string

prin1-to-string object → string

princ-to-string object → string

Arguments and Values:
object—an object.

array—a generalized boolean.
```

base—a radix.

write-to-string, prin1-to-string, princ-to-string

```
case—a symbol of type (member :upcase :downcase :capitalize).

circle—a generalized boolean.

escape—a generalized boolean.

gensym—a generalized boolean.

length—a non-negative integer, or nil.

level—a non-negative integer, or nil.

lines—a non-negative integer, or nil.

miser-width—a non-negative integer, or nil.

pprint-dispatch—a pprint dispatch table.

pretty—a generalized boolean.

radix—a generalized boolean.

readably—a generalized boolean.

right-margin—a non-negative integer, or nil.

string—a string.
```

Description:

write-to-string, prin1-to-string, and princ-to-string are used to create a *string* consisting of the printed representation of *object*. *Object* is effectively printed as if by write, prin1, or princ, respectively, and the *characters* that would be output are made into a *string*.

write-to-string is the general output function. It has the ability to specify all the parameters applicable to the printing of *object*.

prin1-to-string acts like write-to-string with :escape t, that is, escape characters are written where appropriate.

princ-to-string acts like write-to-string with :escape nil :readably nil. Thus no escape characters are written.

All other keywords that would be specified to **write-to-string** are default values when **prin1-to-string** or **princ-to-string** is invoked.

The meanings and defaults for the keyword arguments to **write-to-string** are the same as those for **write**.

Examples:

```
(prin1-to-string "abc") \rightarrow "\"abc\""
```

```
(princ-to-string "abc") 
ightarrow "abc"
```

Affected By:

```
*print-escape*, *print-radix*, *print-base*, *print-circle*, *print-pretty*, *print-level*, *print-length*, *print-case*, *print-gensym*, *print-array*, *read-default-float-format*.
```

See Also:

write

Notes:

```
(write-to-string object {key argument}*)

\[
\begin{align*}
& (with-output-to-string (#1=#:string-stream) \\
& (write object :stream #1# {key argument}*))
\end{align*}

(princ-to-string object)
\[
\begin{align*}
& (with-output-to-string (string-stream) \\
& (princ object string-stream))
\end{align*}

(prin1-to-string object)
\[
\begin{align*}
& (with-output-to-string (string-stream) \\
& (prin1 object string-stream))
\end{align*}
\]
```

print-array

Variable

Value Type:

a generalized boolean.

Initial Value:

implementation-dependent.

Description:

Controls the format in which arrays are printed. If it is false, the contents of arrays other than strings are never printed. Instead, arrays are printed in a concise form using #< that gives enough information for the user to be able to identify the array, but does not include the entire array contents. If it is true, non-string arrays are printed using #(...), #*, or #nA syntax.

Affected By:

The implementation.

See Also:

Section 2.4.8.3 (Sharpsign Left-Parenthesis), Section 2.4.8.20 (Sharpsign Less-Than-Sign)

print-base, *print-radix*

Variable

Value Type:

print-base—a radix. *print-radix*—a generalized boolean.

Initial Value:

The initial value of *print-base* is 10. The initial value of *print-radix* is false.

Description:

print-base and *print-radix* control the printing of rationals. The value of *print-base* is called the current output base.

The value of *print-base* is the radix in which the printer will print rationals. For radices above 10, letters of the alphabet are used to represent digits above 9.

If the value of *print-radix* is true, the printer will print a radix specifier to indicate the radix in which it is printing a rational number. The radix specifier is always printed using lowercase letters. If *print-base* is 2, 8, or 16, then the radix specifier used is #b, #o, or #x, respectively. For integers, base ten is indicated by a trailing decimal point instead of a leading radix specifier; for ratios, #10r is used.

Examples:

```
(let ((*print-base* 24.) (*print-radix* t))
   (print 23.))
> #24rN
\rightarrow 23
 (setq *print-base* 10) 
ightarrow 10
 (setq *print-radix* nil) \rightarrow NIL
 (dotimes (i 35)
    (let ((*print-base* (+ i 2)))
                                                 ;print the decimal number 40
                                                 ; in each base from 2 to 36
       (write 40)
       (if (zerop (mod i 10)) (terpri) (format t " "))))
▷ 1111 220 130 104 55 50 44 40 37 34
▷ 31 2C 2A 28 26 24 22 20 1J 1I

→ 1H 1G 1F 1E 1D 1C 1B 1A 19 18

▷ 17 16 15 14
\rightarrow NIL
 (dolist (pb '(2 3 8 10 16))
```

```
(let ((*print-radix* t) ;print the integer 10 and (*print-base* pb)) ;the ratio 1/10 in bases 2, (format t "~&~S ~S~%" 10 1/10))) ;3, 8, 10, 16

▷ #b1010 #b1/1010

▷ #3r101 #3r1/101

▷ #012 #01/12

▷ 10. #10r1/10

▷ #xA #x1/A

→ NIL
```

Affected By:

Might be bound by format, and write, write-to-string.

See Also:

format, write, write-to-string

print-case

Variable

Value Type:

One of the *symbols* :upcase, :downcase, or :capitalize.

Initial Value:

The symbol :upcase.

Description:

The *value* of *print-case* controls the case (upper, lower, or mixed) in which to print any uppercase characters in the names of *symbols* when vertical-bar syntax is not used.

print-case has an effect at all times when the *value* of *print-escape* is *false*. *print-case* also has an effect when the *value* of *print-escape* is *true* unless inside an escape context (*i.e.*, unless between *vertical-bars* or after a *slash*).

Examples:

```
(defun test-print-case ()
  (dolist (*print-case* '(:upcase :downcase :capitalize))
        (format t "~&~S ~S~%" 'this-and-that '|And-something-elSE|)))

→ TEST-PC
;; Although the choice of which characters to escape is specified by
;; *PRINT-CASE*, the choice of how to escape those characters
;; (i.e., whether single escapes or multiple escapes are used)
;; is implementation-dependent. The examples here show two of the
;; many valid ways in which escaping might appear.
```

```
(test-print-case) ; Implementation A
▷ THIS-AND-THAT | And-something-elSE|
▷ this-and-that a\n\d-\s\o\m\e\t\h\i\n\g-\e\lse
▷ This-And-That A\n\d-\s\o\m\e\t\h\i\n\g-\e\lse
→ NIL
(test-print-case) ; Implementation B
▷ THIS-AND-THAT | And-something-elSE|
▷ this-and-that a|nd-something-el|se
▷ This-And-That A|nd-something-el|se
□ This-And-That A|nd-something-el|se
→ NII.
```

See Also:

write

Notes:

read normally converts lowercase characters appearing in *symbols* to corresponding uppercase characters, so that internally print names normally contain only uppercase characters.

If *print-escape* is true, lowercase characters in the name of a symbol are always printed in lowercase, and are preceded by a single escape character or enclosed by multiple escape characters; uppercase characters in the name of a symbol are printed in upper case, in lower case, or in mixed case so as to capitalize words, according to the value of *print-case*. The convention for what constitutes a "word" is the same as for string-capitalize.

print-circle

Variable

Value Type:

a generalized boolean.

Initial Value:

false.

Description:

Controls the attempt to detect circularity and sharing in an *object* being printed.

If *false*, the printing process merely proceeds by recursive descent without attempting to detect circularity and sharing.

If true, the printer will endeavor to detect cycles and sharing in the structure to be printed, and to use #n= and #n# syntax to indicate the circularities or shared components.

If true, a user-defined **print-object** method can print objects to the supplied stream using **write**, **prin1**, **princ**, or **format** and expect circularities and sharing to be detected and printed using the

#n# syntax. If a user-defined **print-object** method prints to a stream other than the one that was supplied, then circularity detection starts over for that stream.

Note that implementations should not use #n# notation when the Lisp reader would automatically assure sharing without it (e.g., as happens with interned symbols).

Examples:

```
(let ((a (list 1 2 3)))
   (setf (cdddr a) a)
   (let ((*print-circle* t))
        (write a)
        :done))
▷ #1=(1 2 3 . #1#)
→ :DONE
```

See Also:

write

Notes:

An attempt to print a circular structure with *print-circle* set to nil may lead to looping behavior and failure to terminate.

print-escape

Variable

Value Type:

a generalized boolean.

Initial Value:

true.

Description:

If false, escape characters and package prefixes are not output when an expression is printed.

If *true*, an attempt is made to print an *expression* in such a way that it can be read again to produce an **equal** *expression*. (This is only a guideline; not a requirement. See *print-readably*.)

For more specific details of how the *value* of *print-escape* affects the printing of certain *types*, see Section 22.1.3 (Default Print-Object Methods).

Examples:

```
(let ((*print-escape* t)) (write #\a))
```

Affected By:

princ, prin1, format

See Also:

write, readtable-case

Notes:

princ effectively binds *print-escape* to false. prin1 effectively binds *print-escape* to true.

print-gensym

Variable

Value Type:

a generalized boolean.

Initial Value:

true.

Description:

Controls whether the prefix "#:" is printed before apparently uninterned symbols. The prefix is printed before such symbols if and only if the value of *print-gensym* is true.

Examples:

```
(let ((*print-gensym* nil))
  (print (gensym)))
▷ G6040
→ #:G6040
```

See Also:

write, *print-escape*

print-level, *print-length*

print-level, *print-length*

Variable

Value Type:

a non-negative integer, or nil.

Initial Value:

nil.

Description:

print-level controls how many levels deep a nested object will print. If it is false, then no control is exercised. Otherwise, it is an integer indicating the maximum level to be printed. An object to be printed is at level 0; its components (as of a list or vector) are at level 1; and so on. If an object to be recursively printed has components and is at a level equal to or greater than the value of *print-level*, then the object is printed as "#".

print-length controls how many elements at a given level are printed. If it is *false*, there is no limit to the number of components printed. Otherwise, it is an *integer* indicating the maximum number of *elements* of an *object* to be printed. If exceeded, the printer will print "..." in place of the other *elements*. In the case of a *dotted list*, if the *list* contains exactly as many *elements* as the *value* of *print-length*, the terminating *atom* is printed rather than printing "..."

print-level and *print-length* affect the printing of an any *object* printed with a list-like syntax. They do not affect the printing of *symbols*, *strings*, and *bit vectors*.

Examples:

```
(\mathsf{setq}\ \mathsf{a}\ \texttt{'(1}\ (2\ (3\ (4\ (5\ (6)))))))\ \to\ (1\ (2\ (3\ (4\ (5\ (6))))))
 (dotimes (i 8)
   (let ((*print-level* i))
      (format t "~&~D - ~S~%" i a)))
⊳ 0 - #

    □ 1 - (1 #)

▷ 3 - (1 (2 (3 #)))
▷ 4 - (1 (2 (3 (4 #))))
▷ 5 - (1 (2 (3 (4 (5 #)))))
▷ 6 - (1 (2 (3 (4 (5 (6)))))
▷ 7 - (1 (2 (3 (4 (5 (6))))))

ightarrow NIL
 (setq a '(1 2 3 4 5 6)) \rightarrow (1 2 3 4 5 6)
 (dotimes (i 7)
   (let ((*print-length* i))
```

```
(format t "~&~D - ~S~%" i a)))
▷ 0 - (...)
▷ 1 - (1 ...)
▷ 2 - (1 2 ...)
▷ 3 - (1 2 3 ...)
▷ 4 - (1 2 3 4 ...)

▷ 5 - (1 2 3 4 5 6)

ightarrow NIL
(dolist (level-length '((0 1) (1 1) (1 2) (1 3) (1 4)
                         (2 1) (2 2) (2 3) (3 2) (3 3) (3 4)))
 (let ((*print-level* (first level-length))
       (*print-length* (second level-length)))
   (format t "~&~D ~D - ~S~%"
           *print-level* *print-length*
           '(if (member x y) (+ (car x) 3) '(foo . \#(a b c d "Baz"))))))

    ○ 1 - #
▷ 1 1 - (IF ...)
▷ 1 2 - (IF # ...)
▷ 1 3 - (IF # # ...)
▷ 1 4 - (IF # # #)
▷ 2 1 - (IF ...)
\triangleright 2 2 - (IF (MEMBER X ...) ...)

▷ 2 3 - (IF (MEMBER X Y) (+ # 3) ...)

▷ 3 2 - (IF (MEMBER X ...) ...)

\triangleright 3 3 - (IF (MEMBER X Y) (+ (CAR X) 3) ...)
\triangleright 3 4 - (IF (MEMBER X Y) (+ (CAR X) 3) '(FOO . #(A B C D ...)))

ightarrow NIL
```

See Also:

write

print-lines

Variable

Value Type:

a non-negative *integer*, or **nil**.

Initial Value:

nil.

Description:

When the *value* of *print-lines* is other than nil, it is a limit on the number of output lines produced when something is pretty printed. If an attempt is made to go beyond that many lines, ".." is printed at the end of the last line followed by all of the suffixes (closing delimiters) that are pending to be printed.

Examples:

Notes:

The "..." notation is intentionally different than the "..." notation used for level abbreviation, so that the two different situations can be visually distinguished.

This notation is used to increase the likelihood that the *Lisp reader* will signal an error if an attempt is later made to read the abbreviated output. Note however that if the truncation occurs in a *string*, as in "This string has been trunc..", the problem situation cannot be detected later and no such error will be signaled.

print-miser-width

Variable

Value Type:

a non-negative integer, or nil.

Initial Value:

 $implementation\hbox{-} dependent$

Description:

If it is not nil, the *pretty printer* switches to a compact style of output (called miser style) whenever the width available for printing a substructure is less than or equal to this many *ems*.

print-pprint-dispatch

Variable

Value Type:

a pprint dispatch table.

Initial Value:

implementation-dependent, but the initial entries all use a special class of priorities that have the property that they are less than every priority that can be specified using **set-pprint-dispatch**, so that the initial contents of any entry can be overridden.

Description:

The pprint dispatch table which currently controls the pretty printer.

See Also:

print-pretty, Section 22.2.1.4 (Pretty Print Dispatch Tables)

Notes:

The intent is that the initial value of this variable should cause 'traditional' pretty printing of code. In general, however, you can put a value in *print-pprint-dispatch* that makes pretty-printed output look exactly like non-pretty-printed output. Setting *print-pretty* to true just causes the functions contained in the current pprint dispatch table to have priority over normal print-object methods; it has no magic way of enforcing that those functions actually produce pretty output. For details, see Section 22.2.1.4 (Pretty Print Dispatch Tables).

print-pretty

Variable

Value Type:

a generalized boolean.

Initial Value:

implementation-dependent.

Description:

Controls whether the Lisp printer calls the pretty printer.

If it is false, the $pretty\ printer$ is not used and a minimum of $whitespace_1$ is output when printing an expression.

If it is true, the $pretty\ printer$ is used, and the $Lisp\ printer$ will endeavor to insert extra $whitespace_1$ where appropriate to make expressions more readable.

print-pretty has an effect even when the value of *print-escape* is false.

Examples:

```
(setq *print-pretty* 'nil) 
ightarrow NIL
 (progn (write '(let ((a 1) (b 2) (c 3)) (+ a b c))) nil)
▷ (LET ((A 1) (B 2) (C 3)) (+ A B C))

ightarrow NIL
 (let ((*print-pretty* t))
   (progn (write '(let ((a 1) (b 2) (c 3)) (+ a b c))) nil))
(B 2)
        (C 3))
   (+ A B C))
;; Note that the first two expressions printed by this next form
;; differ from the second two only in whether escape characters are printed.
;; In all four cases, extra whitespace is inserted by the pretty printer.
 (flet ((test (x)
          (let ((*print-pretty* t))
             (print x)
             (format t "~%~S " x)
            (terpri) (princ x) (princ " ")
             (format t "~%~A " x))))
  (test '#'(lambda () (list "a" # 'c #'d))))
▷ #'(LAMBDA ()
      (LIST "a" # 'C #'D))
▷ #'(LAMBDA ()
      (LIST "a" # 'C #'D))
▷ #'(LAMBDA ()
      (LIST a b 'C #'D))
▷ #'(LAMBDA ()
    (LIST a b 'C #'D))
\rightarrow \, {\tt NIL}
```

write

print-readably

Variable

Value Type:

a generalized boolean.

Initial Value:

false.

Description:

If *print-readably* is true, some special rules for printing objects go into effect. Specifically, printing any object O_1 produces a printed representation that, when seen by the Lisp reader while the standard readtable is in effect, will produce an object O_2 that is similar to O_1 . The printed representation produced might or might not be the same as the printed representation produced when *print-readably* is false. If printing an object readably is not possible, an error of type print-not-readable is signaled rather than using a syntax (e.g., the "#<" syntax) that would not be readable by the same implementation. If the value of some other printer control variable is such that these requirements would be violated, the value of that other variable is ignored.

Specifically, if *print-readably* is true, printing proceeds as if *print-escape*, *print-array*, and *print-gensym* were also true, and as if *print-length*, *print-level*, and *print-lines* were false.

If *print-readably* is false, the normal rules for printing and the normal interpretations of other printer control variables are in effect.

Individual *methods* for **print-object**, including user-defined *methods*, are responsible for implementing these requirements.

If *read-eval* is *false* and *print-readably* is *true*, any such method that would output a reference to the "#." *reader macro* will either output something else or will signal an error (as described above).

Examples:

```
(setf (gethash table 1) 'one) 
ightarrow ONE
 (setf (gethash table 2) 'two) 
ightarrow TWO
;; Implementation A
 (let ((*print-readably* t)) (print table))
 Error: Can't print #<HASH-TABLE EQL 0/120 32005763> readably.
;; Implementation B
;; No standardized #S notation for hash tables is defined,
;; but there might be an implementation-defined notation.
 (let ((*print-readably* t)) (print table))

▷ #S(HASH-TABLE :TEST EQL :SIZE 120 :CONTENTS (1 ONE 2 TWO))

\rightarrow #<HASH-TABLE EQL 0/120 32005763>
;; Implementation C
;; Note that #. notation can only be used if *READ-EVAL* is true.
;; If *READ-EVAL* were false, this same implementation might have to
;; signal an error unless it had yet another printing strategy to fall
;; back on.
 (let ((*print-readably* t)) (print table))
▶ #.(LET ((HASH-TABLE (MAKE-HASH-TABLE)))
      (SETF (GETHASH 1 HASH-TABLE) ONE)
      (SETF (GETHASH 2 HASH-TABLE) TWO)
      HASH-TABLE)
\rightarrow #<HASH-TABLE EQL 0/120 32005763>
```

write, print-unreadable-object

Notes:

The rules for "similarity" imply that #A or #(syntax cannot be used for arrays of element type other than t. An implementation will have to use another syntax or signal an error of type print-not-readable.

print-right-margin

Variable

Value Type:

a non-negative integer, or nil.

Initial Value:

nil.

Description:

If it is non-nil, it specifies the right margin (as integer number of ems) to use when the pretty printer is making layout decisions.

If it is **ni**l, the right margin is taken to be the maximum line length such that output can be displayed without wraparound or truncation. If this cannot be determined, an *implementation-dependent* value is used.

Notes:

This measure is in units of *ems* in order to be compatible with *implementation-defined* variable-width fonts while still not requiring the language to provide support for fonts.

print-not-readable

Condition Type

Class Precedence List:

print-not-readable, error, serious-condition, condition, t

Description:

The type print-not-readable consists of error conditions that occur during output while *print-readably* is true, as a result of attempting to write a printed representation with the Lisp printer that would not be correctly read back with the Lisp reader. The object which could not be printed is initialized by the :object initialization argument to make-condition, and is accessed by the function print-not-readable-object.

See Also:

print-not-readable-object

print-not-readable-object

Function

Syntax:

print-not-readable-object condition \rightarrow object

Arguments and Values:

condition—a condition of type print-not-readable.

object—an object.

Description:

Returns the *object* that could not be printed readably in the situation represented by *condition*.

See Also:

print-not-readable, Chapter 9 (Conditions)

format Function

Syntax:

format destination control-string &rest args ightarrow result

Arguments and Values:

destination—nil, t, a stream, or a string with a fill pointer.

control-string—a format control.

args—format arguments for control-string.

result—if destination is non-nil, then nil; otherwise, a string.

Description:

format produces formatted output by outputting the characters of *control-string* and observing that a *tilde* introduces a directive. The character after the tilde, possibly preceded by prefix parameters and modifiers, specifies what kind of formatting is desired. Most directives use one or more elements of *args* to create their output.

If destination is a string, a stream, or t, then the result is nil. Otherwise, the result is a string containing the 'output.'

format is useful for producing nicely formatted text, producing good-looking messages, and so on. **format** can generate and return a *string* or output to *destination*.

For details on how the *control-string* is interpreted, see Section 22.3 (Formatted Output).

Affected By:

standard-output, *print-escape*, *print-radix*, *print-base*, *print-circle*, *print-pretty*, *print-level*, *print-length*, *print-case*, *print-gensym*, *print-array*.

Exceptional Situations:

If destination is a string with a fill pointer, the consequences are undefined if destructive modifications are performed directly on the string during the dynamic extent of the call.
